

12.1. 40 CFR 122.21(r)(12) - Non-Water Quality Environmental and Other Impacts Study

This section was prepared by Wood Environment & Infrastructure, Inc.

12.2. INTRODUCTION

In conjunction with 40 Code of Federal Regulations (CFR) §122 and 125, the USEPA promulgated new regulations regarding the NPDES - Final Regulations to Establish Requirements for Cooling Water Intake Structures at Existing Facilities and Amend Requirements at Phase I Facilities (the Rule). The Rule establishes requirements under Section §316(b) of the CWA to ensure that location, design, construction, and capacity of CWIS reflect the best technology available for minimizing adverse environmental impacts. The purpose of this action is to reduce impingement and entrainment of fish and other aquatic organisms at CWIS used by power generation and manufacturing facilities to withdraw cooling water.

Section 122.21(r)(12) of the Rule requires the owner or operator of a facility with a CWIS that withdraws greater than 125 MGD AIF to a detailed facility-specific discussion of the changes in non-water quality environmental and other impacts attributed to each technology and operational measure considered in paragraph (r)(10) of the Rule, Comprehensive Technical Feasibility and Cost Evaluation Study, including both impacts increased and impacts decreased. The study that must be submitted for the facility under 40 CFR §122.21(r)(12) includes the following:

- ▶ Estimates of changes to energy consumption;
- ▶ Estimates of air pollutant emissions and of the human health and environmental impacts associated with such emissions;
- ▶ Estimates of changes in noise;
- ▶ A discussion of impacts to safety, including documentation of the potential for plumes, icing, and availability of emergency cooling water;
- ▶ A discussion of facility reliability, including but not limited to facility availability, production of steam, impacts to production based on process unit heating or cooling, and reliability due to cooling water availability;
- ▶ Significant changes in consumption of water; and
- ▶ A discussion of all reasonable attempts to mitigate each of these factors.

Ameren's LEC is a coal-fired facility and is therefore, not subject to requirements relevant to nuclear facilities.

The following sections present the information required pursuant to 40 CFR §122.21(r)(12) for Ameren's LEC.

12.3. BACKGROUND

The LEC is located adjacent to the Missouri River near Labadie, Missouri which is approximately 35 miles west of St. Louis, in Franklin County (Figure 12.1). LEC is located on the south bank of the Missouri River at river mile 57.5.

The LEC operates year-round as a baseload facility. The plant consists of four generating units with a net capability of 2,580 MW. Over the six-year period of 2008-2013, the average capacity factor for the four units combined was 81.9%, with capacity factors of the individual units ranging from 80.7% to 82.7%. Operation of the plant with respect to Section §316(b) is subject to the conditions of NPDES Permit No. MO-0004812 issued by the MDNR.

The LEC currently utilizes a once-through cooling water system to condense turbine exhaust steam and to provide plant auxiliary cooling water. Cooling water for all four units is withdrawn from the Missouri River via a single shoreline CWIS located on the right descending bank of the river. The CWIS currently has eight intake bays, two for each unit.

Water level elevations at the intakes typically range from 450 feet at design low water level to 484 feet at high water but have reached a maximum level of 490 feet and a minimum low level of 446 feet. The mean water level is 455 feet.

The LEC's circulating water pumps are vertical pumps installed in wet pit intake bays. The flow rate provided by the constant speed pumps is dependent on river level. An increase in river elevation reduces pumping head required and increases the pump flow rate. The total intake structure is designed for a flow rate of 2,240 cfs at the normal river elevation of 455.0 ft. This corresponds to approximately 1,005,400 gpm or 125,750 gpm per pump. At the design low water level of 450 feet the total design flow is 2,104 cfs. This corresponds to 944,300 gpm or 118,000 gpm per pump.

12.4. TECHNOLOGIES AND OPERATIONAL MEASURES CONSIDERED IN THE (R)(10) ANALYSIS

40 CFR §122.21(r)(10) requires the owner or operator of an existing facility that withdraws greater than 125 MGD AIF must develop for submission a Comprehensive Technical Feasibility and Cost Evaluation Study that assesses the technical feasibility, practicality and incremental costs of candidate entrainment control technologies. This study, referred to as the (r)(10) study, was conducted for the LEC and evaluated a range of candidate entrainment control technologies (including an evaluation of technical feasibility of closed-cycle cooling and fine mesh screens with a mesh size of 2 millimeters [mm] or smaller), reuse of water, and potential alternate sources of cooling water (groundwater). The (r)(10) study concluded that the cooling water technologies feasible and practical for consideration at the LEC are:

- ▶ Mechanical Draft Cooling Towers, and
- ▶ Fine Mesh Modified Traveling Screens

These feasible and practical technologies retained for consideration in the (r)(11) and (r)(12) reports are described in the following sections.

12.4.1 Mechanical Draft Cooling Towers

Wet cooling towers reduce the temperature of a water stream by extracting heat from the water and emitting it to the atmosphere via evaporation of a small portion of the water stream. Mechanical draft towers use fans to draw air through falling circulated water. The water falls over fill surfaces, which helps increase the contact time between the water and the air, maximizing heat transfer between the two. A portion of the water evaporates, which cools the remainder of the water.

Closed cycle cooling technologies, including mechanical draft cooling towers, significantly reduce entrainment losses because source waterbody withdrawal rates are significantly reduced or eliminated. The proposed cooling tower system at the LEC would be a closed loop, with the necessary make-up water provided via groundwater collector wells, eliminating the need for cooling water withdrawal from the Missouri River.

The preliminary design for a mechanical draft cooling tower retrofit at the LEC would include the installation of four new cooling towers, with 20 cells per tower. Multiple-cell towers can be linear, square, or round depending upon the shape of the individual cells and whether the air inlets are located on the sides or bottoms of the cells. The most efficient and common designs are long rectangular configurations, as utilized in the proposed design at the LEC (Figure 12.2).

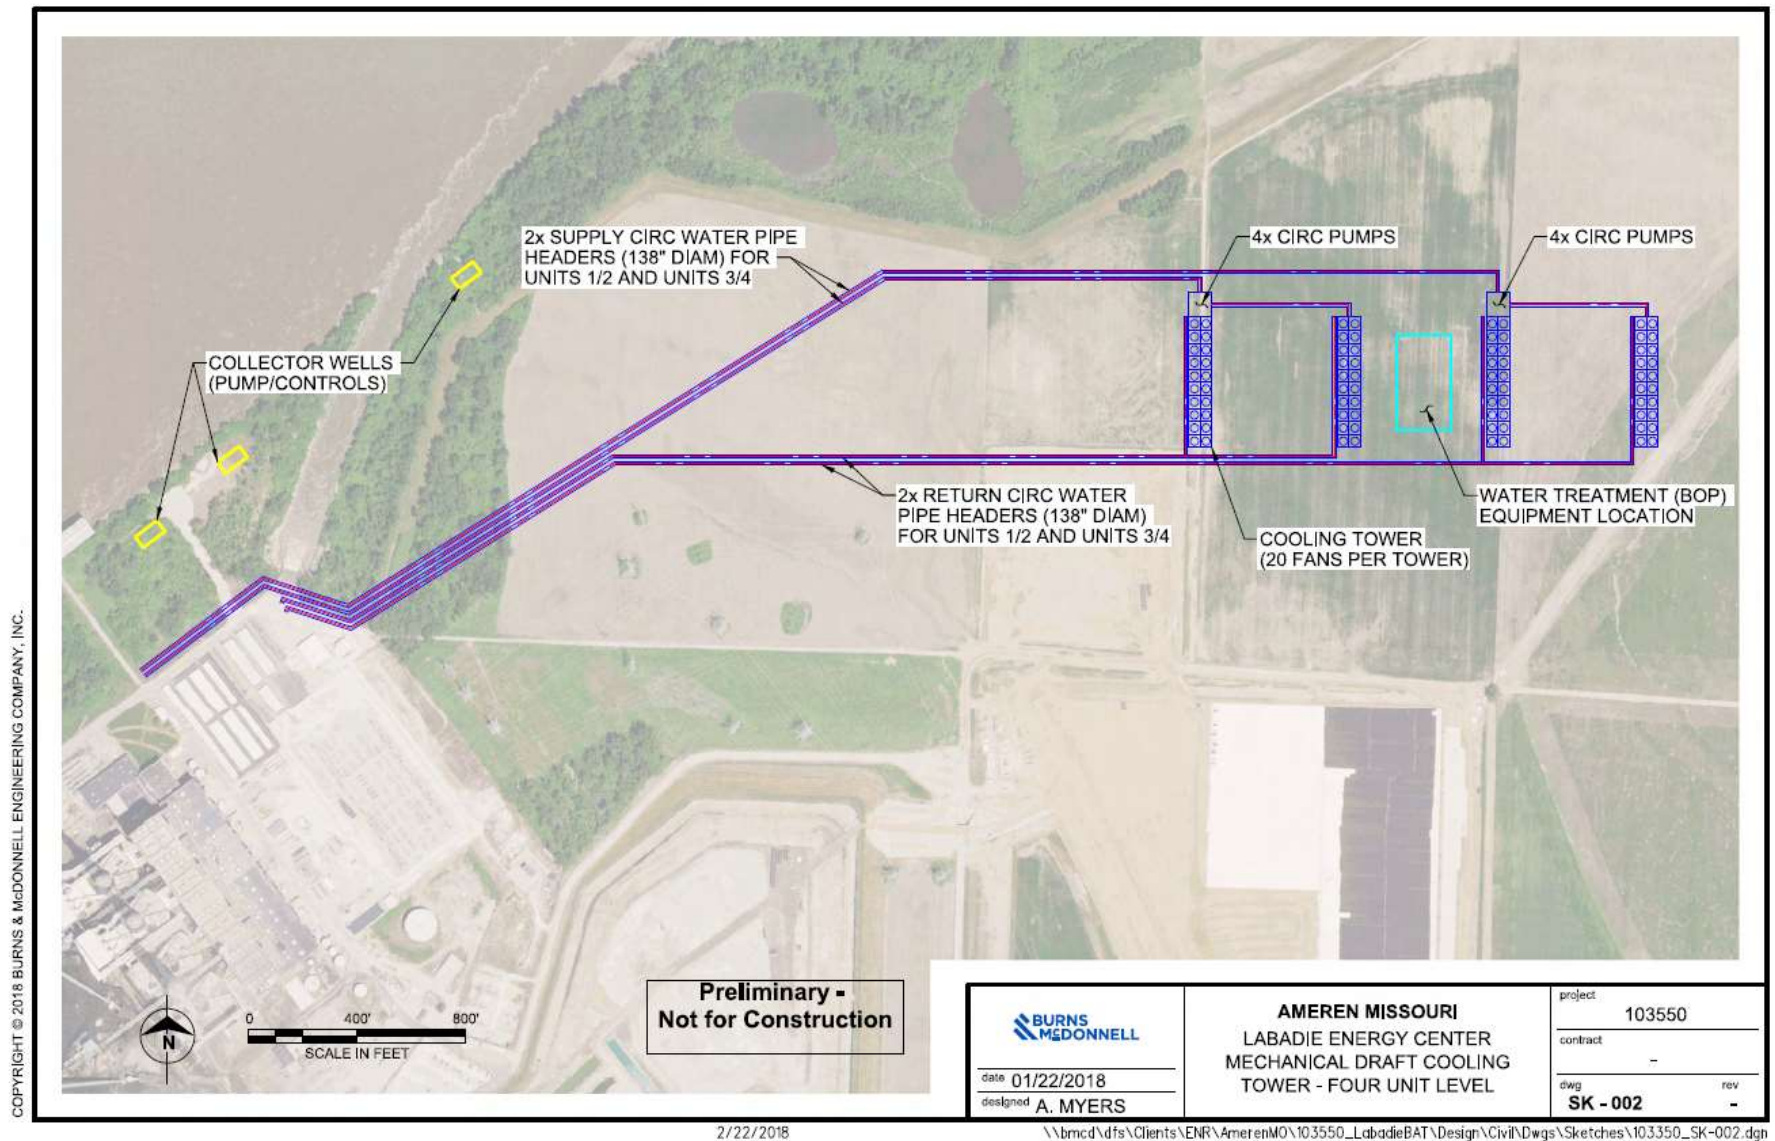

Figure 12.2. Proposed Mechanical Draft Cooling Tower Configuration
(Source: Burns and McDonnell, 2018)

While other cooling tower arrangements were evaluated and considered to be feasible, they were more costly. Therefore, because mechanical draft cooling towers were both lower cost and feasible and practical, it was retained as the technology for use in (r)(11) and (12).

12.4.2 Fine Mesh Modified Traveling Screens

Fine mesh (equal to 2.0 mm or smaller) screen technologies provide entrainment protection through exclusion and survivability of aquatic organisms. Exclusion of an organism is based on the screen mesh dimensions and the size of the organism. Survivability is based on the force with which the organisms are pushed against the screen (through-screen velocity) and the handling characteristics of the system that removes the organism from the screen and returns it to the source waterbody.

The preferred alternatives for installation of fine mesh at the LEC allow for the replacement of the current 3/8-inch mesh traveling water screens with 2.0 mm or smaller screen mesh while maintaining both the current cooling water flow and a through-screen velocity equal to or less than the current calculated velocity. Two modifications to the existing intake structure were determined to meet these criteria and were retained for further consideration:

- ▶ 2.0 mm Dual-Flow Fine Mesh Modified Traveling Water Screen Conversion
- ▶ 0.5 mm Thru-Flow Fine Mesh Modified Traveling Water Screen in an Expanded Cooling Water Intake Structure

As both fine mesh traveling screen modifications involve the continued use of the existing CWIS and related infrastructure in accordance with §125.94(c)(5), many of the non-water quality impacts associated with these modifications are indistinguishable. Therefore, in the (r)(12) analysis, they are generally referred to collectively under the broader designation of Fine Mesh Modified Traveling Screens. In instances where non-water quality impacts between the two screen modification options differ, they are broken out and assessed separately.

12.4.2.1 2.0 mm Dual-Flow Fine Mesh Screen Conversion

Analysis of available screen alternatives indicates that it is likely feasible to install dual flow 2.0 mm x 2.0 mm fine mesh conversion screens in the existing CWIS, shown in Figure 12.3, and increase screen surface area such that enough cooling water flow could be provided at the existing through-screen velocity to operate the plant as it currently operates. The existing CWIS would need to be modified to accommodate the dual-flow screens. At a minimum, the floor slab upstream from the existing screen will have to be partially demolished. Other modifications may also be required or beneficial. For instance, it would be beneficial to locate the screen as far downstream from the stop gates as possible, which may require modification of concrete support beams within the CWIS framing structure.

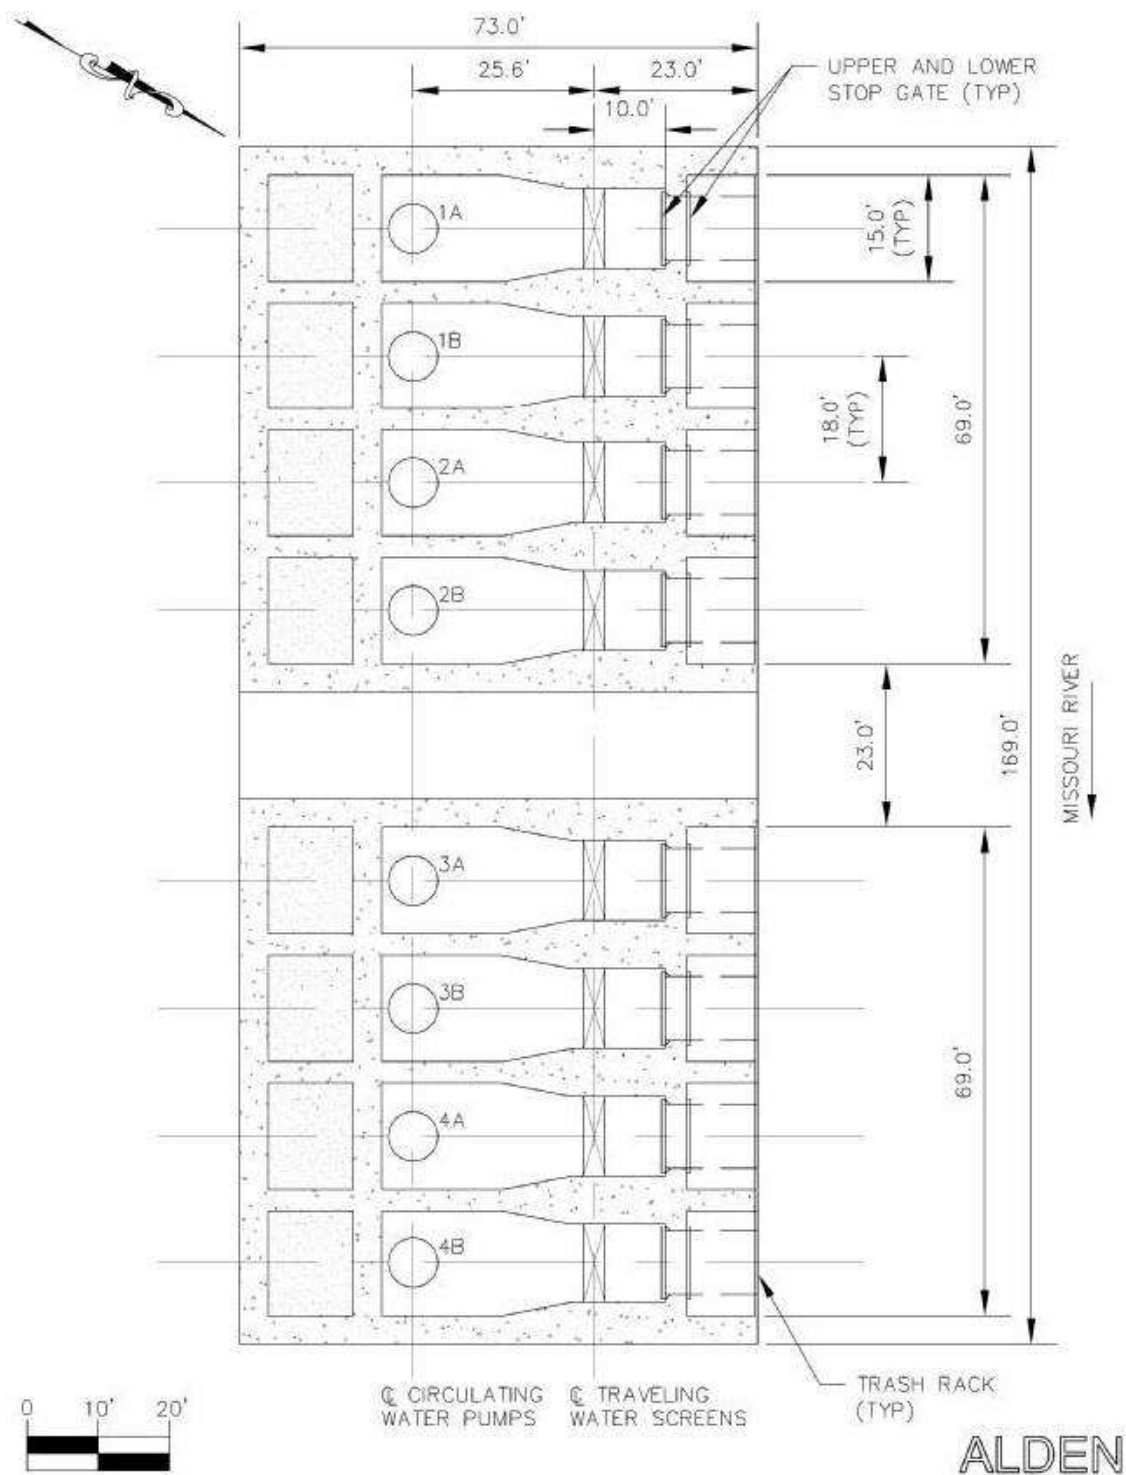

Figure 12.3. Existing CWIS Plan Detail
(Source: Alden 2005)

12.4.2.2 0.5 mm Fine Mesh Screen in an Expanded Cooling Water Intake Structure

The mesh size preferred to maximize exclusion is 0.5 mm x 0.5 mm fine mesh. Several alternative arrangements for the expansion of the CWIS to accommodate 0.5 mm fine mesh were conceptualized. For this level of hypothetical analysis, a single alternative was selected for further development, in which 14 new screen bays would be constructed to accommodate the flow and velocity requirements (Figure 12.4). The proposed design entails the construction of new intake bays with trash racks, gates and traveling water screens flanking the existing CWIS. Forebays would be constructed to channel water into the existing CWIS bays. The trash racks and traveling water screens would be removed from the existing bays. The existing pumps and condenser piping system would remain and continue to operate. The total length of the new intake would be approximately 420 feet long. A fish handling and return system would be installed for all bays and a warm water, recirculating, piping system would be installed to minimize the potential for icing.

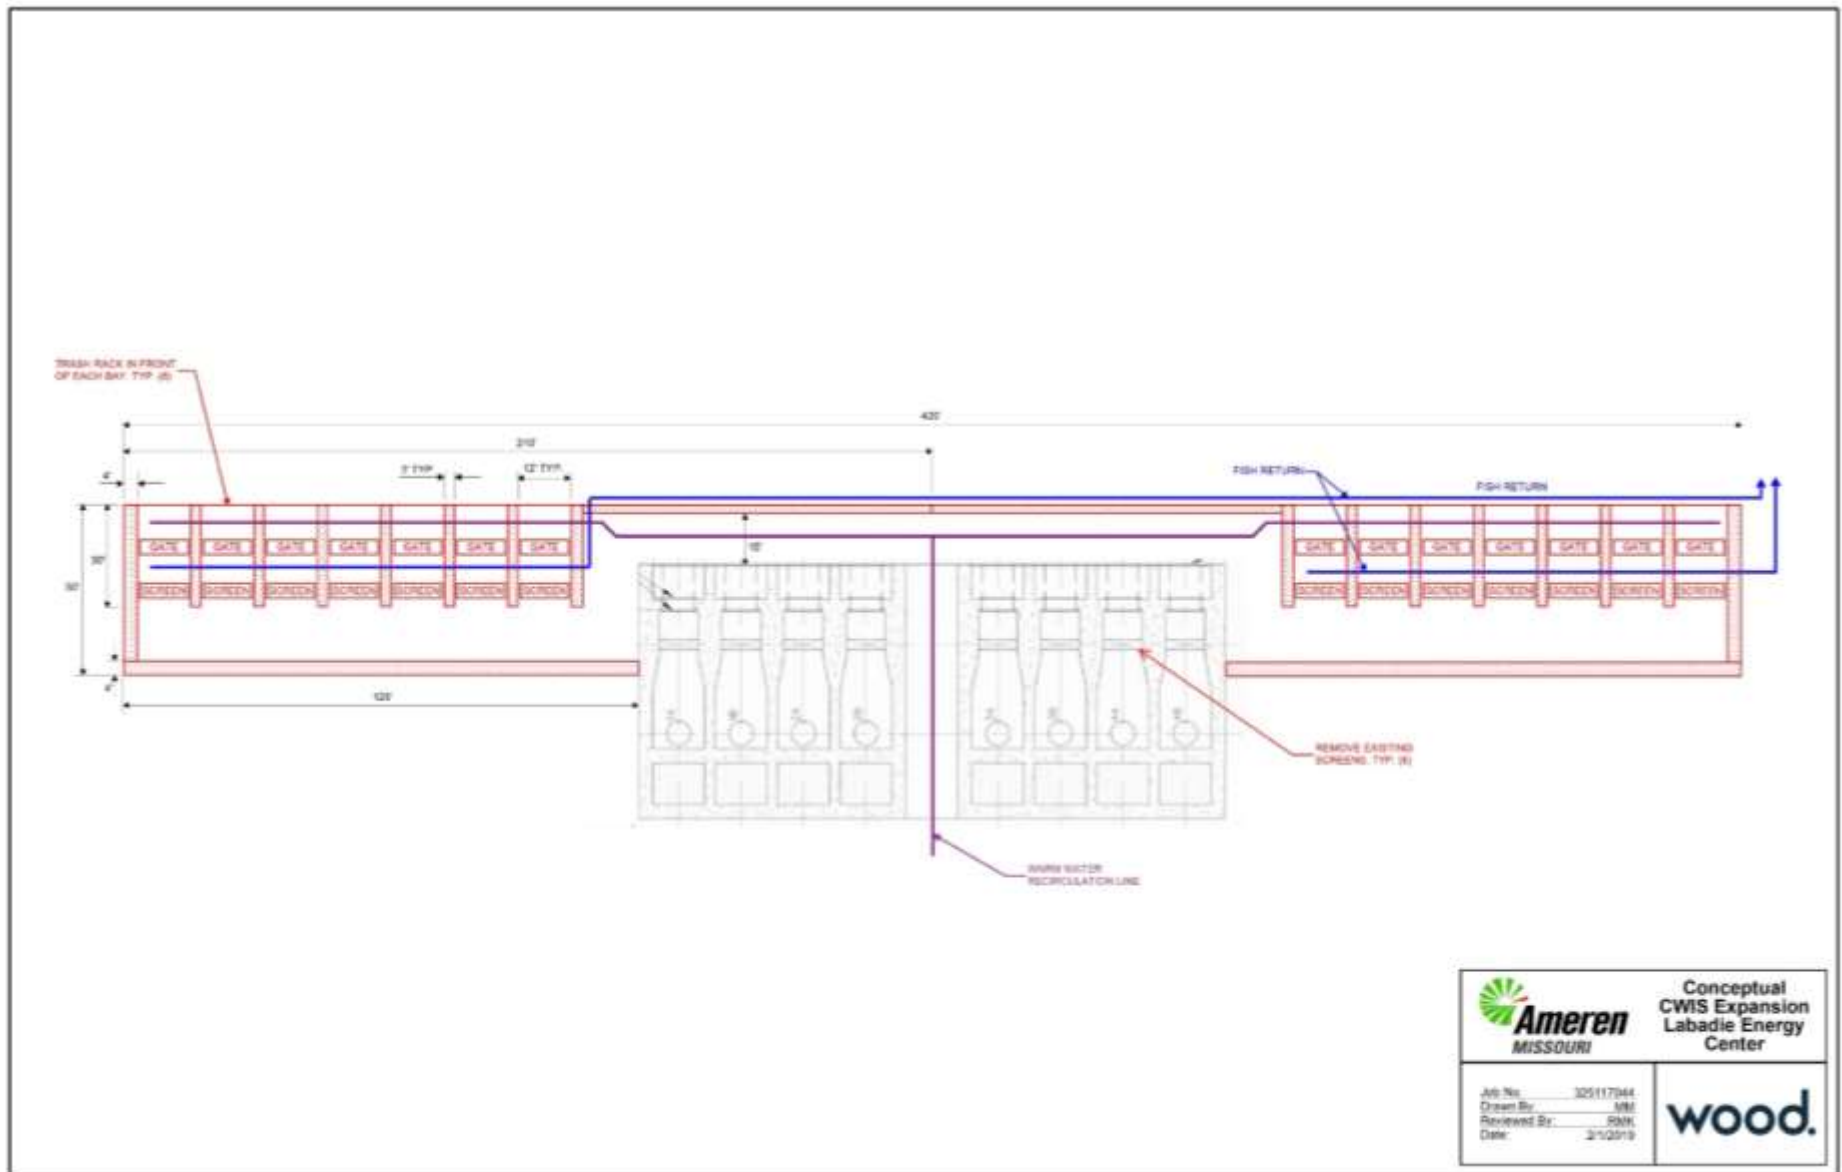

Figure 12.4. Proposed CWIS Expansion to Accommodate 0.5 mm Fine Mesh Screens

12.5. ANALYSIS OF NON-WATER QUALITY IMPACTS

40 CFR §122.21(r)(12) requires the owner or operator of an existing facility that withdraws greater than 125 MGD AIF to develop a detailed facility specific discussion of the changes in non-water quality environmental and other impacts attributed to each technology and operational measure considered in the (r)(10) study, including both impacts increased and impacts decreased. This Rule addresses six types of non-water quality impacts and mitigation. Required elements of the non-water quality impacts analysis include the following:

- ▶ energy consumption,
- ▶ air pollutant emissions,
- ▶ noise,
- ▶ safety concerns,
- ▶ facility reliability, and
- ▶ consumptive water use.

The following analysis provides the detailed description of the non-water quality impacts and mitigation measures considered for each of the cooling water technologies determined optimal for the LEC in the (r)(10) study.

12.5.1 Energy Consumption

The following section provides an estimate of changes to energy consumption associated with the utilization of Mechanical Draft Cooling Towers and Fine Mesh Modified Traveling Screens at the LEC, in accordance with §122.21(r)(12)(i):

Estimates of changes to energy consumption, including but not limited to auxiliary power consumption and turbine backpressure energy penalty

12.5.1.1 Mechanical Draft Cooling Towers

The preliminary design for a mechanical draft cooling tower retrofit at the LEC would include the installation of four new cooling towers, with 20 cells per tower. Retrofitting to closed-cycle cooling would result in a net loss in plant output due to both the increased auxiliary power consumption from the additional electrical demand to operate the cooling towers, and the decrease in power output due to turbine efficiency loss.

Auxiliary loads would increase with the addition of cooling tower fans, larger pumps for circulating the cooling water, and various balance of plant (BOP) auxiliary equipment including raw water makeup

pumps, chemical feed pumps, water treatment equipment, and blowdown pumps. Power requirements for the circulating water pumps and fans to operate the cooling towers were determined to be:

- ▶ Eight new circulating water pumps (2 per cooling tower) at approximately 4,200 hp each.
- ▶ Eighty cooling tower fans (20 per cooling tower) at approximately 250 hp each.

The auxiliary loads for this equipment were provided by Burns and McDonnell (2019). The calculations of net auxiliary load also take into account the reduction in auxiliary load due to the decommissioning of some existing equipment that would no longer be operating (i.e. existing intake pumps). Table 12.1 provides a breakdown of the estimated net auxiliary load increase for a four-unit mechanical draft cooling tower retrofit during average summer conditions (28.9 MW) and average winter conditions (23.0 MW).

Table 12.1. Estimated Auxiliary Load for Four-Unit Mechanical Draft Cooling Tower (MW)

Equipment	Average Summer Condition	Average Winter Condition
New Cooling Tower Fans	14.9	9.0
New Circulating Water Pumps	25.0	25.0
Other New BOP Auxiliary Equipment	1.4	1.4
Total New Auxiliary Load	41.3	35.4
Existing Auxiliary Loads to be Removed	12.4	12.4
Net Additional Auxiliary Load	28.9	23.0

Source: Burns and McDonnell, 2019

Turbine efficiency loss is the sum of loss output among all the steam turbines due to increased circulating water temperatures. Typically, especially during warmer summer conditions, cooling towers do not cool the circulating water to the same temperature as surface water used in once-through cooling. As a result, the steam is not cooled as effectively, leading to a higher steam turbine backpressure and a loss of generating efficiency. According to specifications provided by Burns and McDonnell, the turbine efficiency loss for a four-unit mechanical draft cooling tower retrofit at the LEC is estimated to be approximately 9.9 MW during average summer conditions (Burns and McDonnell, 2019). During colder, winter conditions, there is little to no generation inefficiency. The total net plant output loss is the sum of the net auxiliary load and the turbine efficiency loss. The total net plant output

loss, also referred to as the energy penalty, is estimated to be 38.8 MW during average summer conditions and 23.0 MW during average winter conditions (Table 12.2).

Table 12.2. Energy Penalty for Four-Unit Mechanical Draft Cooling Tower (MW)

	Average Summer Condition	Average Winter Condition
Net Additional Auxiliary Load	28.9	23.0
Turbine Efficiency Loss	9.9	0
Total Net Plant Output Loss (Energy Penalty)	38.8	23.0

Source: Burns and McDonnell, 2019

12.5.1.2 Fine Mesh Modified Traveling Screens

The utilization of fine mesh modified traveling screens would have no impact on steam turbine efficiency, so changes to total plant output would be limited to additional auxiliary loads. New auxiliary loads for the two screen modification options are described below.

12.5.1.2.1 2.0 mm Dual-Flow Fine Mesh Screen Conversion

The power requirements for the 2.0 mm dual-flow fine mesh screens are expected to be similar to the power requirements of the anticipated future baseline operating condition of impingement compliant modified traveling water screens that would be continuously rotating and washing. The existing pumps and condenser piping system would remain and continue to operate. Therefore, there would be no appreciable changes to auxiliary load or energy consumption under this alternative.

12.5.1.2.2 0.5 mm Fine Mesh Screen in an Expanded Cooling Water Intake Structure

The use of 0.5 mm fine mesh screens in an expanded CWIS would require an additional auxiliary load for new screen drives and spray pumps. Power requirements for the additional equipment were determined to be:

- ▶ 14 new screen drives at approximately 15 hp each.
- ▶ Five spray pumps at approximately 200 hp each.

This results in an additional auxiliary load of 157 kilowatts (kW) for the new screen drives and 746 kW for the new spray pumps, when operating at full capacity. Therefore, the maximum additional auxiliary load under this alternative is estimated to be 903 kW or approximately 0.9 MW. The existing pumps and condenser piping system, which have an auxiliary load of 12.4 MW, would remain and continue to operate, resulting in a total auxiliary load loss of 13.3 MW.

12.5.2 Air Pollutant Emissions and Human Health and Environmental Impacts

The following section provides an estimate of air pollutant emissions and associated impacts resulting from the utilization of Mechanical Draft Cooling Towers and Fine Mesh Modified Traveling Screens at the LEC, in accordance with §122.21(r)(12)(ii):

Estimates of air pollutant emissions and of the human health and environmental impacts associated with such emissions

Air quality is protected by the Clean Air Act (CAA) and air quality standards established by the USEPA. As required by the CAA, the USEPA has established National Ambient Air Quality Standards for pollutants considered harmful to public health and the environment. These are carbon monoxide, lead, nitrogen dioxide, ozone, particulate matter (PM), particulate matter less than 10 microns in diameter (PM₁₀), particulate matter less than 2.5 microns in diameter (PM_{2.5}), and sulfur dioxide (SO₂). The LEC is not located within a designated nonattainment or maintenance area for carbon monoxide, lead, nitrogen dioxide, PM₁₀, or SO₂; however, the northeastern corner of Franklin County, where the LEC is located, has been designated as nonattainment (marginal) for 8-hour ozone. Franklin County was also designated as nonattainment (moderate) for PM_{2.5} by the 1997 standard but was found to be in attainment in October 2018 and was therefore redesignated as a maintenance area by the USEPA (EPA, 2019).

12.5.2.1 Mechanical Draft Cooling Towers

12.5.2.1.1 Air Pollutant Emissions

Cooling Tower Drift Emissions

Mechanical draft cooling towers emit particulate matter through the generation of drift emissions. During the evaporative cooling process, a small portion of liquid water droplets are carried along with the evaporated water (cooling tower drift) in the tower exhaust. Minerals and any dissolved or suspended solids in the make-up water stream can become entrained in these liquid water droplets and these constituents can be emitted as total PM, (PM₁₀), and PM_{2.5}. Based on the Thermal Discharge Best Available Technology Economically Achievable Analysis (BAT Analysis) for the LEC, the emissions potential for particulate matter based on a four-cooling-tower design with four cycles of concentration (COC) at LEC is estimated to be between 5 tons per year (tpy) and 20 tpy, depending on the COC design and the concentration of total dissolved solids (TDS) in the makeup water (Burns and McDonnell, 2018).

The LEC is an existing major source of air emissions permitted under the CAA, and cooling towers would be considered modifications to this existing major source. If the PM emissions from modifications to the existing major source exceed the major modification thresholds, the cooling towers would be subject to Federal permit review including Prevention of Significant Deterioration (PSD). Table 12.3 provides the maximum potential PM emissions from the proposed cooling towers and the national PSD significance levels (40 CFR § 52.21). While the estimate from the BAT Analysis

approximates a range of total PM emissions at the LEC, it has not been determined what amount of that total would be PM₁₀ and PM_{2.5}. Therefore, the maximum potential emissions for these specific pollutants were provided under the assumption that all PM emissions were both PM₁₀ and PM_{2.5}.

Table 12.3. Estimated PM Emissions and PSD Significance Levels

Pollutant	Maximum Potential Cooling Tower Emissions (tpy)	PSD Significance Levels (tpy)
PM	20	25
PM ₁₀	20	15
PM _{2.5}	20	10

Source: Burns and McDonnell, 2018

As shown in Table 12.3, at the top end of the estimated range (20 tpy), the increase in total PM from the cooling towers would be below the PSD significance level of 25 tpy. However, under the assumption that all PM is comprised exclusively of either PM₁₀ and/or PM_{2.5}, the emissions of these pollutants exceed the significance levels of 15 tpy and 10 tpy, respectively. Under this scenario, a PSD major modification permit would be required. However, this assumption is highly conservative and if this technology is selected, a more detailed evaluation of PM₁₀ and PM_{2.5} emissions would be needed to determine if a PSD major modification permit would be required.

Emissions Associated with Replacement Energy Generation

A cooling tower retrofit would result in lost energy from both construction downtime and the energy penalty discussed in Section 12.5.1.1. As such, replacement energy would have to be made up by the LEC and/or the surrounding generating facilities to meet the regional transmission organization requirements. Assuming that such replacement energy is provided by fossil fuel generation facilities, this would require that these facilities burn additional fuel, thereby emitting additional carbon dioxide (CO₂), SO₂, nitrogen oxides (NO_x), and PM.

LEC is owned and operated by Ameren Missouri, a regulated, investor-owned public utility that participates in the MISO regional transmission organization. A social cost study was conducted by Veritas Economic Consulting to determine differences in fuel consumption and associated costs and emissions for various entrainment reduction technologies at the LEC (Appendix 10E). To estimate the power system effects from capacity losses for the LEC and within the regional transmission organization, conditions were specified and input into the Ameren Missouri module of a 316(b)-focused power system model called the Environmental Policy Simulation Model (EPSM). The process was implemented by carrying out the following steps within EPSM's power system module:

1. Estimate the hourly energy penalty
2. Specify total hourly load

3. Operate model consistent with load and unit characteristics
4. Create scenarios representing LEC's conversion and ongoing operations
5. Run EPSM model to identify counterfactual dispatch
6. Calculate differences in fuel consumption, emissions, and costs

The calculated changes in power generation due to the operation of four mechanical draft cooling towers at LEC would lead to changes in fuel consumption and CO₂, SO₂, NO_x, and PM emissions in the Ameren Missouri Region. As each generating unit would be converted to closed-cycle cooling individually, over the course of approximately four years, the additional fuel consumption and associated air emissions would increase throughout the conversion years as additional units are converted. Post conversion operations, ongoing after Conversion Year 4, reflect the increased emissions due to replacement energy generation needed to account for the energy penalty associated with closed-cycle cooling for all four units.

Increases in emissions during the first conversion year are estimated to amount to 47,510 tons of CO₂, 230 tons of SO₂, 30 tons of NO_x, and 1,990 tons of PM (Table 12.4). Emissions would increase incrementally over the following conversion years until all units have been converted to a closed-cycle cooling tower system. Following Conversion Year 4, and continuing in ongoing years, increases in emissions would amount to approximately 221,600 tons of CO₂, 490 tons of SO₂, 124 tons of NO_x, and 9,290 tons of PM annually.

Table 12.4. Incremental Indirect Emissions Due to the Reduced Generating Capacity from Closed-Cycle Cooling

Pollutant	Tons				
	Conversion Year 1	Conversion Year 2	Conversion Year 3	Conversion Year 4	Ongoing Year
CO ₂	47,510	98,790	154,000	208,300	221,600
SO ₂	230	330	430	480	490
NO _x	30	80	110	119	124
PM	1,990	4,140	6,460	8,730	9,290

Source: Veritas, 2019 (Appendix 10E)

12.5.2.1.2 Human Health Impacts

According to the EPA, the size of PM emissions is directly linked to their potential for causing human health impacts. PM₁₀ poses the greatest problems, because particles smaller than 10 micrometers can, once inhaled, enter the lungs and cause serious health effects. Exposure to such particles can affect both the respiratory and circulatory systems. Numerous scientific studies have linked PM pollution exposure to a variety of problems, including:

- ▶ premature death in people with heart or lung disease;
- ▶ nonfatal heart attacks;
- ▶ irregular heartbeat;
- ▶ aggravated asthma;
- ▶ decreased lung function; and
- ▶ increased respiratory symptoms, such as irritation of the airways, coughing or difficulty breathing.

People with pulmonary and respiratory diseases, children, and older adults are the most likely to be affected by PM pollution exposure (EPA, 2018). While the PM emissions from a cooling tower, such as inorganic salts and organic material, likely result in lesser adverse health effects than do combustion-derived particles (i.e. smoke), research has not been able to precisely quantify the contributions of different PM components to human health effects from PM exposure (World Health Organization 2006). Therefore, there is a possibility that increased PM emissions from cooling tower drift can result in impacts to human health.

In 2011, the Electric Power Research Institute (EPRI) conducted a technical study entitled *Net Environmental and Social Effects of Retrofitting Power Plants with Once-Through Cooling to Closed-Cycle Cooling* (Closed-Cycle Cooling Effects Study) (EPRI, 2011a). In the study, potential upper bounds for possible human health impacts associated with increases in PM emissions from cooling tower retrofits were estimated through human health risk assessment. The risk assessment methodology used to evaluate human health impacts was based on the document entitled *Particulate Matter Health Risk Assessment for Selected Urban Areas* (EPA, 2005). This USEPA document describes a series of concentration-response functions developed through evaluation of epidemiological evidence to assess the relationship of PM concentration and health effects responses. The generalized USEPA concentration-response function was used to estimate the increased incidence of the following endpoints that may occur, over and above possible current baseline effects associated with ambient PM:

- ▶ Mortality due to long-term exposure to an increased concentration of PM_{2.5}; and
- ▶ Hospital admissions for treatment of morbidity effects such as heart disease, bronchitis, emphysema, and pneumonia due to exposure to increased concentrations of PM_{2.5} and/or PM that measures between 10 and 2.5 microns in diameter.

EPRI research indicates the EPA's methods and their application in this closed-cycle cooling analysis results in very conservative risk estimates at the high end of the upper bound.

The EPRI study included a risk assessment for 24 power plant facilities, representing a variety of fuel types, climatic regions, waterbody types, and surrounding population density. As PM concentrations are highly dependent upon the makeup and salinity of the cooling water, the representative facilities

were grouped based on waterbody type. To account for populations exposed, they were also categorized into low, medium, and high population densities (Table 12.5).

Table 12.5. EPRI Study Population Density Categories

Population Category	Density (people/square mile) ¹
Low	<100
Medium	100-1,000
High	>1,000

¹Based on year 2000 population data for census tracts within which the facilities are located

Under the criteria outlined in the EPRI study, the LEC would fall into the subgroup characterized by medium population density and a water source consisting of a large river, reservoir, or lake. Although the cooling tower design proposes to use make-up water provided via groundwater collector wells rather than sourcing water from the Missouri River, this category still most accurately represents LEC. TDS in groundwater would be more similar to those in rivers, reservoirs, or lakes than TDS of water bodies in subgroups with higher salinities such as oceans, estuaries, and tidal rivers.

Four of the representative facilities individually analyzed in the risk assessment (Beta Test Plant “D”, Beta Test Plant “E”, Representative Facility “G”, and Representative Facility “J”) also belong to the medium population density and large river, reservoir, or lake water source subgroup. The estimated annual risk of increased mortality and morbidity due to cooling tower PM emissions for these four representative facilities are provided in Table 12.6. Values represent an approximation of the estimated human health risks associated with closed-cycle cooling retrofits.

Table 12.6. Estimated Annual Risk of Increased Mortality and Morbidity due to Cooling Tower PM Emissions

Representative Facility	Annual Mortality (# of Deaths Over Baseline) ¹	Annual Morbidity (# of Hospital Visits Over Baseline) ¹		
		Cardiovascular Disease	Chronic Obstructive Pulmonary Disease	Pneumonia
Beta Test Plant "D"	0.002	0.009	0.0006	0.002
Beta Test Plant "E"	0.01	0.1	0.007	0.02
Representative Facility "G"	0.0007	0.005	0.0001	0.0008
Representative Facility "J"	0.003	0.02	0.001	0.004

¹Values are fractional probabilities of occurrence whereby:

- 0.1= 1 occurrence in 10 years
- 0.01= 1 occurrence in 100 years
- 0.001= 1 occurrence in 1,000 years
- 0.0001= 1 occurrence in 10,000 years

The estimates for all representative facilities in the EPRI study were calculated assuming that mechanical draft evaporative cooling towers are equipped with drift eliminators to limit the drift rate to 0.0005 percent of the circulating water flow rate. Efficient drift eliminators are commonly required for permitting and have also been included in the cooling tower design at the LEC. Therefore, the estimated annual risk of increased mortality due to cooling tower PM emissions from the LEC, based on the risk assessment of similar facilities presented in Table 12.6, is likely in the vicinity of 0.0007 to 0.01 deaths over baseline per year, or conservatively, one death over baseline every 100 years. Cardiovascular disease is the condition with the highest annual morbidity, with the high end approaching 0.1 hospital visit over baseline per year, or one visit every 10 years. The high-end estimates for annual morbidity of Chronic Obstructive Pulmonary Disease, which includes lung diseases like emphysema, chronic bronchitis and asthma, is 0.007 hospital visits over baseline (1 additional visit every 142 years), and for pneumonia is 0.02 hospital visits over baseline (1 additional visit every 50 years).

As discussed in Section 12.5.2.1.1, air pollutants (CO₂, SO₂, NO_x, and additional PM) will be emitted as a result of the replacement energy generation associated with the utilization of cooling towers. Similar to cooling tower PM emissions, these additional air pollutants can cause an increased likelihood of respiratory problems, including inflammation of the lungs, bronchitis, and complications with asthma. However, as the impacts of these air pollutants are not reliably quantifiable and may occur elsewhere in the region, they are not accounted for above. Therefore, there is a potential for minor additional health impacts to occur regionally due to replacement energy generation emissions.

12.5.2.1.3 Environmental Impacts

Increased particulate matter emissions from cooling tower drift may also result in impacts to the environment. PM can be carried over significant distances by wind and then settle on ground or in water. Depending on the chemical composition, the effects of this settling may include:

- ▶ Making freshwater bodies acidic;
- ▶ Changing the nutrient balance in large river basins;
- ▶ Depleting the nutrients in soil;
- ▶ Damaging sensitive forests and farm crops;
- ▶ Affecting the diversity of ecosystems; and
- ▶ Contributing to acid rain effects (EPA, 2018).

In lieu of site-specific detailed modeling, the direction that the PM would settle at the LEC was qualitatively evaluated using wind rose data collected between 2012 and 2019 from the closest meteorological tower at the Washington Airport, located approximately 10 miles east of the proposed location of the cooling towers. Based on this data, PM would typically settle northwest and southeast of the cooling towers, potentially impacting cultivated crops that surround the site, as well as the shoreline vegetation and Missouri River to the northwest.

The amount of salt and mineral drift from cooling towers at the LEC would be minor compared to those of coastal facilities due to the use of freshwater makeup water. PM emissions from cooling tower drift, modeled by EPRI in the Closed-Cycle Cooling Effects Study, were determined to be significantly greater for the higher salinity makeup water withdrawn from oceans, estuaries, and tidal rivers (i.e., average of 388.1 tpy/facility) compared to facilities withdrawing from freshwater (i.e., average of 17.1 tpy/facility) (EPRI 2011a).

Additionally, the U.S. Nuclear Regulatory Commission (NRC) found, in an analysis of 24 licensed nuclear power plants that use wet cooling towers, that the worst-case PM emissions from cooling tower drift only had a minor impact potential. The analysis found that the majority of the deposition from cooling towers occurs in relatively close proximity to the towers. Generally, deposition rates from these cooling towers were below those known to result in measurable adverse impacts on plants, and most nuclear plants showed no indication of deposition effects on agricultural crops or plant communities in the vicinity (NRC, 2013). Therefore, in consideration of the reliance of the LEC cooling towers on freshwater and the prior studies conducted by EPRI and NRC, the impact of cooling tower PM emissions from the LEC on the surrounding environment are expected to be minimal.

In addition to impacts from PM, the construction of the cooling towers would have a direct impact on the terrestrial environment within the footprint of the proposed towers. However, as the lands proposed for cooling tower development at the LEC are made up of cultivated cropland, no rare or sensitive habitats will be directly impacted. There are no National Wetlands Inventory (NWI) mapped wetlands

or surface water bodies within the proposed footprint (Figure 12.5), and while the area is located within designated critical habitat for the federally endangered Indiana bat (*Myotis sodalis*), no suitable habitat is present as there are no trees located within the proposed cooling tower footprint.

12.5.2.2 *Fine Mesh Modified Traveling Screens*

12.5.2.2.1 *2.0 mm Dual-Flow Fine Mesh Screen Conversion*

Modification of the CWIS to accommodate 2.0 mm dual-flow fine mesh screens would require the use of mechanized equipment to demolish portions of the floor slab, which may include the use of barge and tow operations, pile drivers, graders, dozers, dump trucks and other related equipment. As such, localized emissions are expected to result from equipment operation. However, such emissions are anticipated to be short term and minor.

As there would be no appreciable changes to auxiliary load or energy consumption associated with the use of 2.0 mm fine mesh screens, there would be no reduction in generating capacity or increased air emissions resulting from replacement energy generation. Changes in air pollutant emissions due to this technology would be negligible, and no resulting impacts to human health or the environment are anticipated.

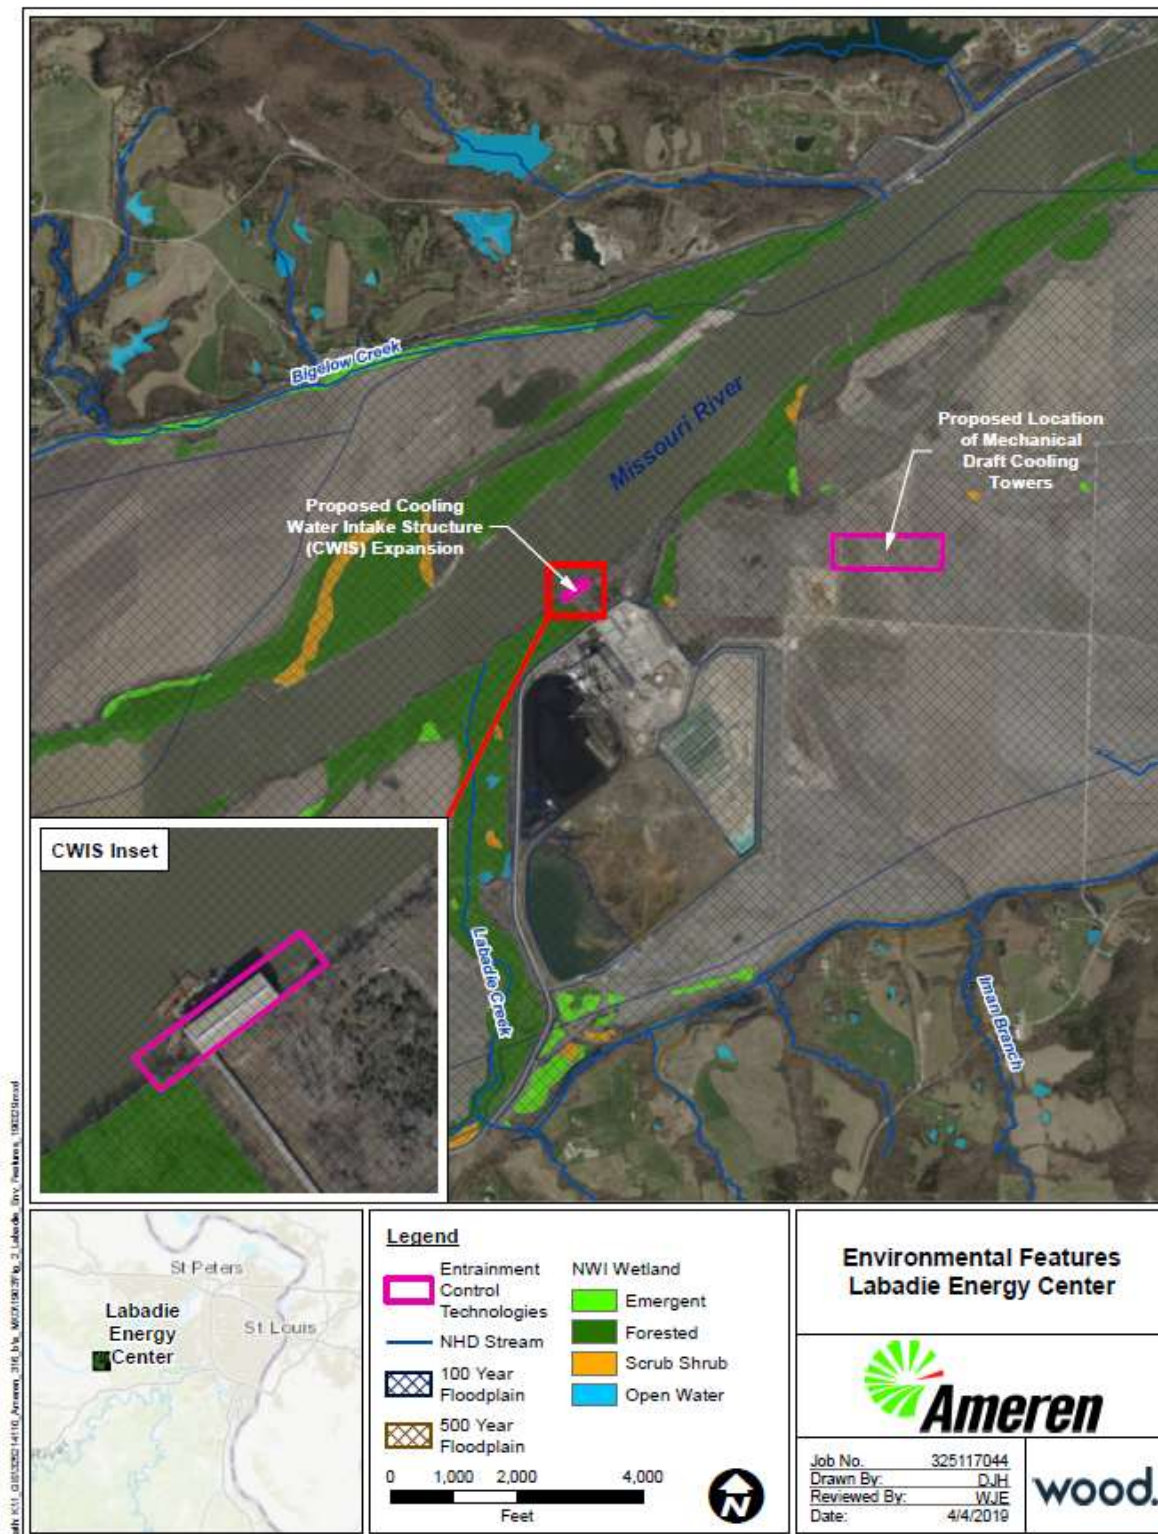

Figure 12.5. Environmental Features in the Vicinity of LEC

12.5.2.2.2 0.5 mm Fine Mesh Screen in an Expanded Cooling Water Intake Structure

Air Pollutant Emissions

The expansion of the CWIS to accommodate 0.5 mm fine mesh screens would require use of mechanized equipment to construct and expand the intake facility. Similar to the 2.0 mm dual-flow modification, localized emissions are expected to result from equipment operation. However, such emissions are anticipated to be short term and minor.

In addition, due to the increased auxiliary load of new screen drives and spray pumps and associated reduced generating capacity, additional air emissions would result from replacement energy generation. The social cost study (Appendix 10E) used the EPSM Ameren Missouri power system module to model changes in regional fuel consumption and CO₂, SO₂, NO_x, and PM emissions resulting from the use of 0.5 mm fine mesh screens in an expanded CWIS at LEC.

Increases in emissions during the conversion year are estimated to amount to 14.64 tons of CO₂, 0.03 tons of SO₂, 0.01 tons of NO_x, and 0.61 tons of PM (Table 12.7). A typical year following the conversion is estimated to have increases of 19.67 tons of CO₂, 0.04 tons of SO₂, 0.01 tons of NO_x, and 0.82 tons PM.

Table 12.7. Incremental Indirect Emissions Due to the Reduced Generating Capacity from 0.5 mm Fine Mesh Screens

Pollutant	Tons	
	Conversion Year	Following Year
CO ₂	14.64	19.67
SO ₂	0.03	0.04
NO _x	0.01	0.01
PM	0.61	0.82

Source: Veritas, 2019 (Appendix 10E)

Human Health Impacts

As previously discussed, air pollutants such as CO₂, SO₂, NO_x, and PM can cause an increased likelihood of respiratory problems. Although impacts from these pollutants are not readily quantifiable, due to the relatively minor increase in air emissions (orders of magnitude less than those associated with cooling towers), human health impacts associated with the utilization of 0.5 mm fine mesh screens in an expanded CWIS are anticipated to be negligible.

Environmental Impacts

Environmental impacts associated with the expansion of the existing CWIS are primarily associated with the construction activities and permanent loss of habitat in the areas where expansion will occur. The current design proposes to extend the CWIS by 125 feet upstream and 125 feet downstream from the current structure boundaries. It will also extend approximately 17 feet further into the river. This will result in the conversion of shoreline habitats and associated wetland and riparian zones along edge of the Missouri River. An NWI mapped freshwater forested/shrub wetland is located within the proposed expansion area to the southwest of the existing CWIS (Figure 12.5). In the event this technology is selected, further evaluation would be required to determine the extent of temporary and permanent impacts to wetland and shoreline habitats. This expansion would also entail extensive environmental reviews and permitting in conjunction with Sections 401/402/404 of the CWA, Section 10 of the Rivers and Harbors Act, Section 106 of the National Historic Preservation Act, and Section 7 of the ESA.

12.5.3 Noise

The following section provides an estimate of changes in noise associated with the utilization of Mechanical Draft Cooling Towers and Fine Mesh Modified Traveling Screens at LEC, in accordance with §122.21(r)(12)(iii):

Estimates of changes in noise

Noise is unwanted or unwelcome sound usually caused by human activity and added to the natural acoustic setting of a locale. It is further defined as sound that disrupts normal activities or that diminishes the quality of the environment. Community response to noise is dependent on the intensity of the sound source, its duration, the proximity of noise-sensitive land uses, and the time of day the noise occurs (i.e., higher sensitivities would be expected during the quieter overnight periods).

Sound is measured in logarithmic units called decibels (dB). Given that the human ear cannot perceive all pitches or frequencies of sound, noise measurements are typically weighted to correspond to the limits of human hearing. This adjusted unit of measure is known as the A-weighted decibel (dBA) which filters out sound in frequencies above and below human hearing. A noise level change of 3 dBA or less is barely perceptible to average human hearing. However, a 5 dBA change in noise level is clearly noticeable. The noise level associated with a 10 dBA change is perceived as being twice as loud; whereas the noise level associated with a 20 dBA change is considered to be four times as loud and would therefore represent a “dramatic change” in loudness.

To account for sound fluctuations, environmental noise is commonly described in terms of the equivalent sound level. The equivalent sound level is the constant noise level that conveys the same noise energy as the actual varying instantaneous sounds over a given period. Fluctuating levels of continuous, background, and/or intermittent noise heard over a specific period are averaged as if they had been a steady sound. The day-night sound level (L_{dn}), expressed in dBA, is the 24-hour average noise level with a 10-dBA correction penalty for the hours between 10 p.m. and 7 a.m. to account for the increased sensitivity of people to noises that occur at night. Typical background day-night noise levels for rural areas is anticipated to range between an L_{dn} of 35 and 50 dB, whereas higher-density

residential and urban areas background noise levels range from 43 dB to 72 dB (EPA, 1974). Background noise levels greater than 65 dBA can interfere with normal conversation, watching television, using a telephone, listening to the radio, and sleeping. Common indoor and outdoor noise levels are listed in Table 12.8.

Table 12.8. Common Indoor and Outdoor Noise Levels

Common Outdoor Noises	Sound Pressure Levels (dB)	Common Indoor Noises
Jet Flyover at 300 meters (984.3 feet)	110	Rock Band at 5 meters (16.4 feet)
Gas Lawn Mower at 1 meter (3.3 feet)	100	Inside Subway Train (New York)
Diesel Truck at 15 meters (49.2 feet)	90	Food Blender at 1 meter (3.3 feet)
Gas Lawn Mower at 30 meters (98.4 feet)	80	Garbage Disposal at 1 meter (3.3 feet)
Commercial Area	70	Shouting at 1 meter (3.3 feet)
Quiet Urban Daytime	60	Vacuum Cleaner at 3 meters (9.8 feet)
Quiet Urban Nighttime	50	Normal Speech at 1 meter (3.3 feet)
Quiet Suburban Nighttime	40	Large Business Office
Quiet Rural Nighttime	30	Dishwasher Next Room
	20	Small Theater, Large Conference Room
	10	Library
	0	Bedroom at Night
		Concert Hall (Background)
		Broadcast and Recording Studio
		Threshold of Hearing

Source: Arizona DOT 2008

Neither the state of Missouri nor Franklin County have passed ordinances to regulate nuisance noise. The EPA 1974 guidelines recommend that L_{dn} not exceed 55 dBA for outdoor residential areas. The U.S. Department of Housing and Urban Development (HUD) considers an L_{dn} of 65 dBA or less to be compatible with residential areas (HUD 1985).

The LEC is located along the south bank of the Missouri River in a rural area. Current ambient noise levels at the LEC are typical of an operating industrial plant. Other noise generating sources in the vicinity of the plant include periodic barge operations or boats on the river and noise from nearby

residential traffic and local farm operations. Overall, the surrounding area is rural with very low density residential development and farms. Klondike Park and sections of the Katy Trail are located directly across the river from LEC. These recreational facilities, as well as several single-family residences in the vicinity, are considered sensitive noise receptors that could be negatively impacted by substantial increases in ambient noise.

12.5.3.1 Mechanical Draft Cooling Towers

Construction of the mechanical draft cooling towers would require use of mechanized equipment, which may include the use of pile drivers, graders, dozers, dump trucks and other related equipment. Sound levels of up to 95 dBA can be expected at a distance of 50 feet from the construction area during use of this equipment (Federal Highway Administration 2016). Based on straight line noise attenuation, it is estimated that maximum construction noise levels of 95 dBA at a distance of 50 feet from the cooling tower construction site would attenuate to 55.4 dBA at the closest portion of the Katy Trail, which also serves as the southern boundary for Klondike Park (Table 12.9). The construction noise would attenuate to 53.8 dBA at the closest residence, located approximately 5,740 feet to the southeast. The locations of the sensitive noise receptors nearest to LEC and the proposed cooling towers are shown in Figure 12.6.

Table 12.9. Attenuation of Cooling Tower Noise at Sensitive Receptors

Sensitive Receptor	Distance from Proposed Cooling Towers (feet)	Construction Noise Level at Receptor (dBA)	Operational Noise Level at Receptor (dBA)
Katy Trail / Boundary of Klondike Park	4,791	55.4	40.4
Klondike Park Conference Center	5,295	54.5	39.5
Closest Residence to Northwest	8,017	50.9	35.9
Closest Residence to Northeast	6,160	53.2	38.2
Closest Residence to South	6,215	53.1	38.1
Closest Residence to Southeast	5,740	53.8	38.8

During operation, mechanical draft cooling towers primarily generate noise from fans and fan drives, as well as falling water. According to industry supplier SPX Corporation, for conventional mechanical draft cooling towers, sound levels of approximately 60 dBA are expected at a distance of 500 feet (as

cited in Tetra Tech, 2010a). Based on straight line noise attenuation, it is estimated that noise levels from the cooling towers would attenuate to 38.8 dBA at the nearest residence (Table 12.9).

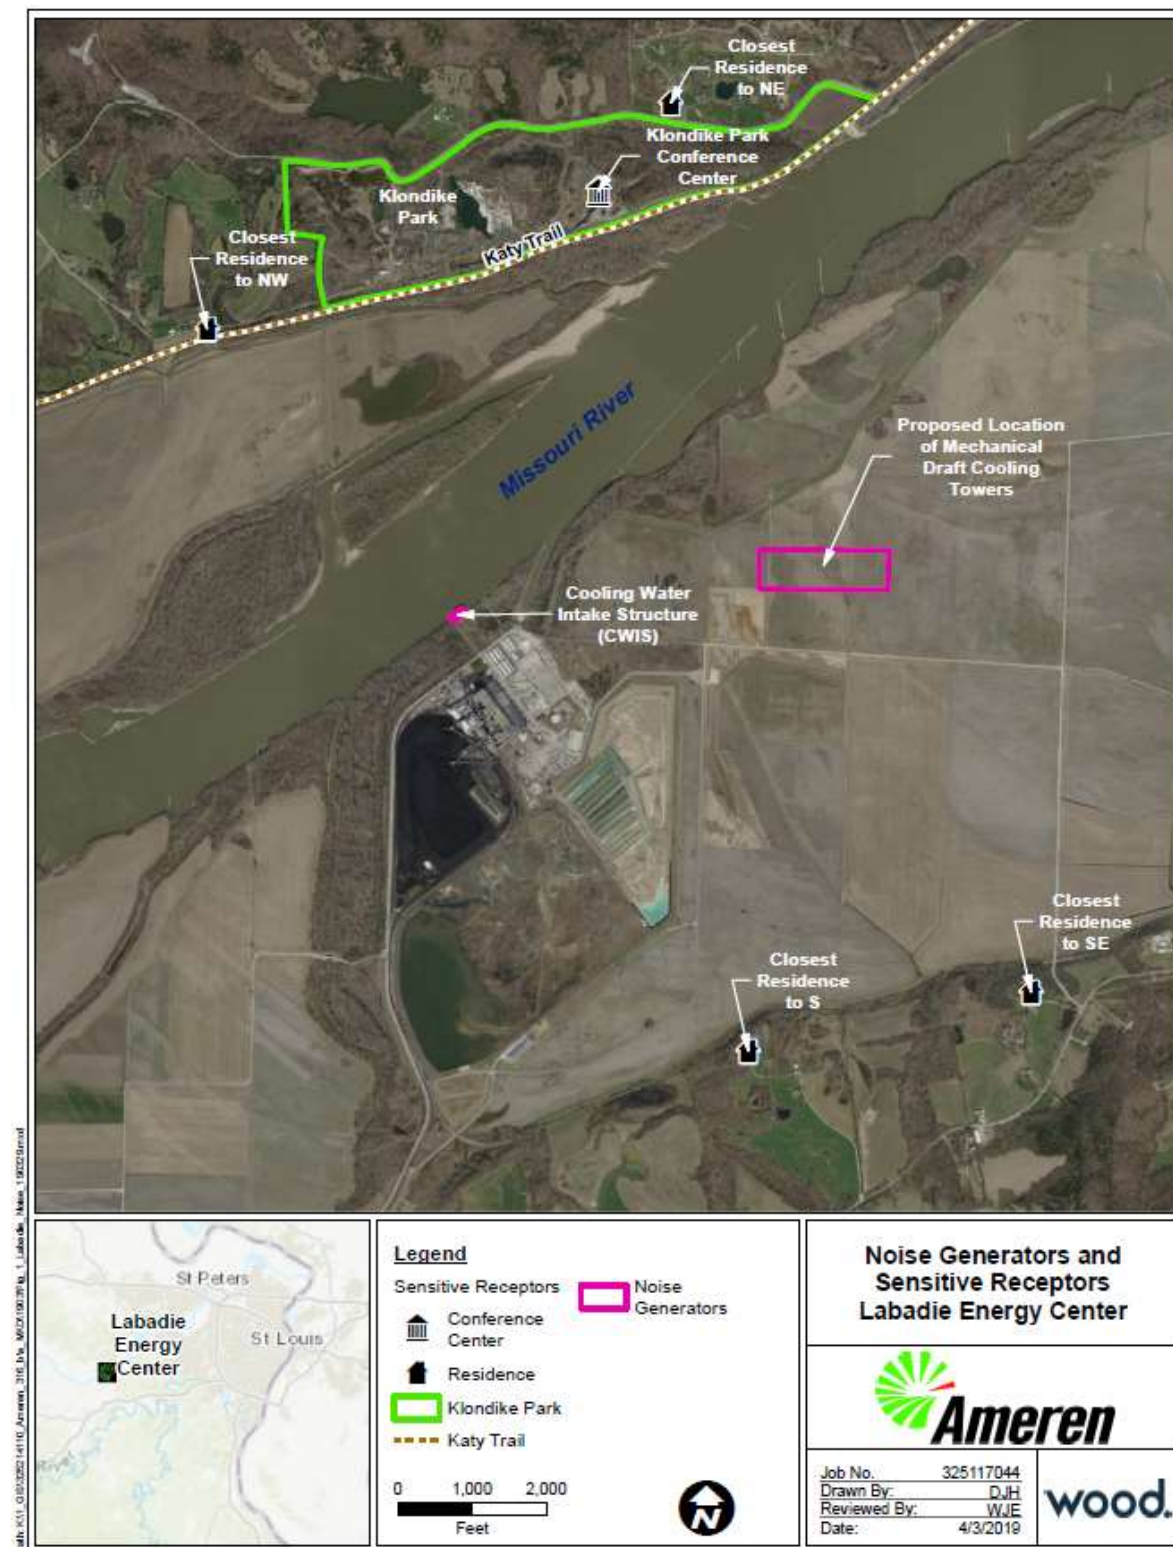

Figure 12.6. Sensitive Noise Receptors in the Vicinity of LEC

Similarly, cooling tower noise would attenuate to 40.3 dBA at the Katy Trail, which also serves as the southern border of Klondike Park, and 39.5 dBA at the Klondike Park Conference Center.

The construction noise level at the closest portion of the Katy Trail and Klondike Park boundary is slightly higher than the EPA L_{dn} guideline of 55 dBA, but lower than the HUD L_{dn} guideline of 65 dBA. Additionally, the construction noise would be intermittent and limited to the approximate 4-year duration of construction, during normal working hours. The noise levels associated with continuous cooling tower operation are below both the EPA L_{dn} guideline of 55 dBA and the HUD L_{dn} guideline of 65 dBA at all sensitive receptors.

With the absence of regulatory noise limits and the significant distance between the proposed cooling towers and the closest sensitive receptors, noise impacts from a cooling tower retrofit at LEC on the surrounding community would be minor. Nuisance noise from the cooling towers would be limited to areas within the LEC property boundary; furthermore, they would be unlikely to add a significant level of noise to an already noisy industrial site. All sensitive receptors are at enough distance that cooling tower noise would attenuate to levels below USEPA guidelines and consistent with background day-night noise levels for rural areas.

12.5.3.2 *Fine Mesh Modified Traveling Screens*

Modification of the existing CWIS to accommodate fine mesh screens would require use of mechanized equipment, which may include the use of barge and tow operations, pile drivers, graders, dozers, dump trucks and other related equipment. Sound levels of up to 95 dBA can be expected at a distance of 50 feet from the construction area during use of this equipment (Federal Highway Administration 2016). Based on straight line noise attenuation, it is estimated that maximum construction noise levels of 95 dBA at a distance of 50 feet from the CWIS construction site would attenuate to 56.2 dBA at the closest portion of the Katy Trail, which also serves as the southern boundary for Klondike Park (Table 12.10). The construction noise would attenuate to 54.8 dBA at the closest residence to the CWIS, located approximately 5,100 feet to the northwest (Figure 12.6).

The construction noise level at the closest portion of the Katy Trail and Klondike Park boundary is slightly higher than the USEPA L_{dn} guideline of 55 dBA, but lower than the HUD L_{dn} guideline of 65 dBA. Additionally, the construction noise would be intermittent and limited to the duration of modification and/or expansion activities, during normal working hours. Construction noise levels at all other sensitive receptors, including all residences, are below both USEPA and HUD L_{dn} guidelines. Once construction activities are complete, operation of the CWIS with the fine mesh modified traveling screens would result in minor localized noise increases associated with the continuous screen rotation and increase in the number of traveling water screens but would not result in appreciable changes at the distance of any sensitive receptors.

Table 12.10. Attenuation of Construction Noise Associated with CWIS Modification at Sensitive Receptors

Sensitive Receptor	Distance from Proposed Cooling Towers (ft)	Noise Level at Receptor (dBA)
Katy Trail / Boundary of Klondike Park	4,345	56.2
Klondike Park Conference Center	5,855	53.6
Closest Residence to Northwest	5,100	54.8
Closest Residence to Northeast	7,515	51.5
Closest Residence to South	7,080	52.0
Closest Residence to Southeast	9,200	49.7

12.5.4 Safety

The following section provides a discussion of safety impacts associated with the utilization of Mechanical Draft Cooling Towers and Fine Mesh Modified Traveling Screens at the LEC, in accordance with §122.21(r)(12)(iv):

A discussion of impacts to safety, including documentation of the potential for plumes, icing, and availability of emergency cooling water

12.5.4.1 Mechanical Draft Cooling Towers

The primary safety concerns associated with the use of mechanical draft cooling towers are vapor plume impacts. Traditional wet cooling towers emit plumes of saturated air which can result in ground fogging and rime icing during cold conditions. These plume impacts are dependent upon weather conditions, and typically occur at ground level when the ambient humidity and moisture emitted in the cooling tower plume combine to create a relative humidity of 100 percent. Icing then occurs under these same conditions, when the ambient temperature is below 32 degrees Fahrenheit. Ground fogging creates safety hazards by reducing visibility, and if dense enough, vapor plumes can even affect radar transmissions and interfere with air traffic control. Rime ice can create hazardous working and driving conditions and can cause damage to structures such as transmission lines.

While the estimated frequency of ground fogging and icing at the LEC were not assessed using a Seasonal Annual Cooling Tower Impact model, the following qualitative analysis of the potential safety

impacts from vapor plumes is provided based on the conditions and surrounding infrastructure at the plant.

Decreased visibility and ice accumulation from vapor plumes could create hazardous working conditions at the LEC, potentially leading to increased worker accidents and injuries. The facility also receives coal shipments via the adjacent railroad southwest of the cooling towers. Icing or fogging could create safety challenges for rail delivery. Increased incidents of ground fogging and icing on State Route 94, located approximately 1.08 miles north of the proposed cooling towers, and Highway T, located approximately 1.15 miles southeast of the proposed cooling towers, could create an increase in hazardous driving conditions and vehicle accidents. Icing of high-capacity transmission lines is also a primary concern at LEC, as rime ice development on these lines would threaten plant operations.

In order to prevent frequent impacts from fogging and icing at the LEC facility and nearby transmission lines and railroad tracks, the design proposes to locate the cooling towers approximately 0.7 miles east of the plant and approximately 0.2 miles northeast of the closest transmission lines (Figure 12.7). The BAT Analysis (Burns and McDonnell, 2018) concluded that constructing the cooling towers at this location, a sufficient distance from the plant, would negate the need for plume abatement. Plume abatement is typically recommended for facilities within a 2-mile radius of an airport or within a 0.5-mile radius of major roads. Cooling tower plumes at the LEC are not anticipated to interfere with air traffic control because the closest airport, Washington Regional Airport, is greater than 5 miles from the proposed tower location. Both roads in the vicinity of the LEC are also outside the 0.5-mile buffer for major roads which accounts for distance required to disperse fog or ice forming plumes plus a generous safety margin (Tetra Tech, 2010b). Additionally, both roads have relatively low traffic volumes, with State Route 94 having an average annual daily traffic (AADT) of 1,462 vehicles, and Highway T having an AADT of 2,801 vehicles (Missouri Department of Transportation, 2016). Therefore, safety impacts due to cooling tower plumes are anticipated to be minimal.

Additionally, the utilization of mechanical draft cooling towers would require additional operation and maintenance worker hours when compared to existing conditions. This would result in an increase in the potential for worker accidents and injuries.

12.5.4.2 *Fine Mesh Modified Traveling Screens*

12.5.4.2.1 *2.0 mm Dual-Flow Fine Mesh Screen Conversion*

The installation of 2.0 mm dual-flow fine mesh screens in the existing CWIS would not directly increase unsafe working conditions. However, the continuous operation of the traveling water screens would require additional operation and maintenance worker hours when compared to existing conditions, increasing the potential for worker accidents and injuries. No other impacts to safety are anticipated with the use of this technology.

12.5.4.2.2 0.5 mm Fine Mesh Screen in an Expanded Cooling Water Intake Structure

Similar to the 2.0 mm dual-flow fine mesh conversion, the continuous operation of the traveling water screens and increase in the number of screens under the 0.5 mm fine mesh alternative would require additional operation and maintenance worker hours, increasing the potential for worker accidents and injuries. In addition, under the proposed design, the expansion of the CWIS would extend 125 feet upstream and 125 feet downstream from the current structure boundaries. It will also extend approximately 17 feet further into the river. This expansion would result in a very minor increase to potential safety hazards for barges and recreational boaters, as slightly more of the river would be obstructed, increasing the possibility of watercraft collisions with the CWIS. However, the width of the Missouri River at the CWIS is just over 1,500 feet. The 17 additional feet the CWIS would extend into the river would be insignificant and would not impact the ability of boats and barges to safely pass.

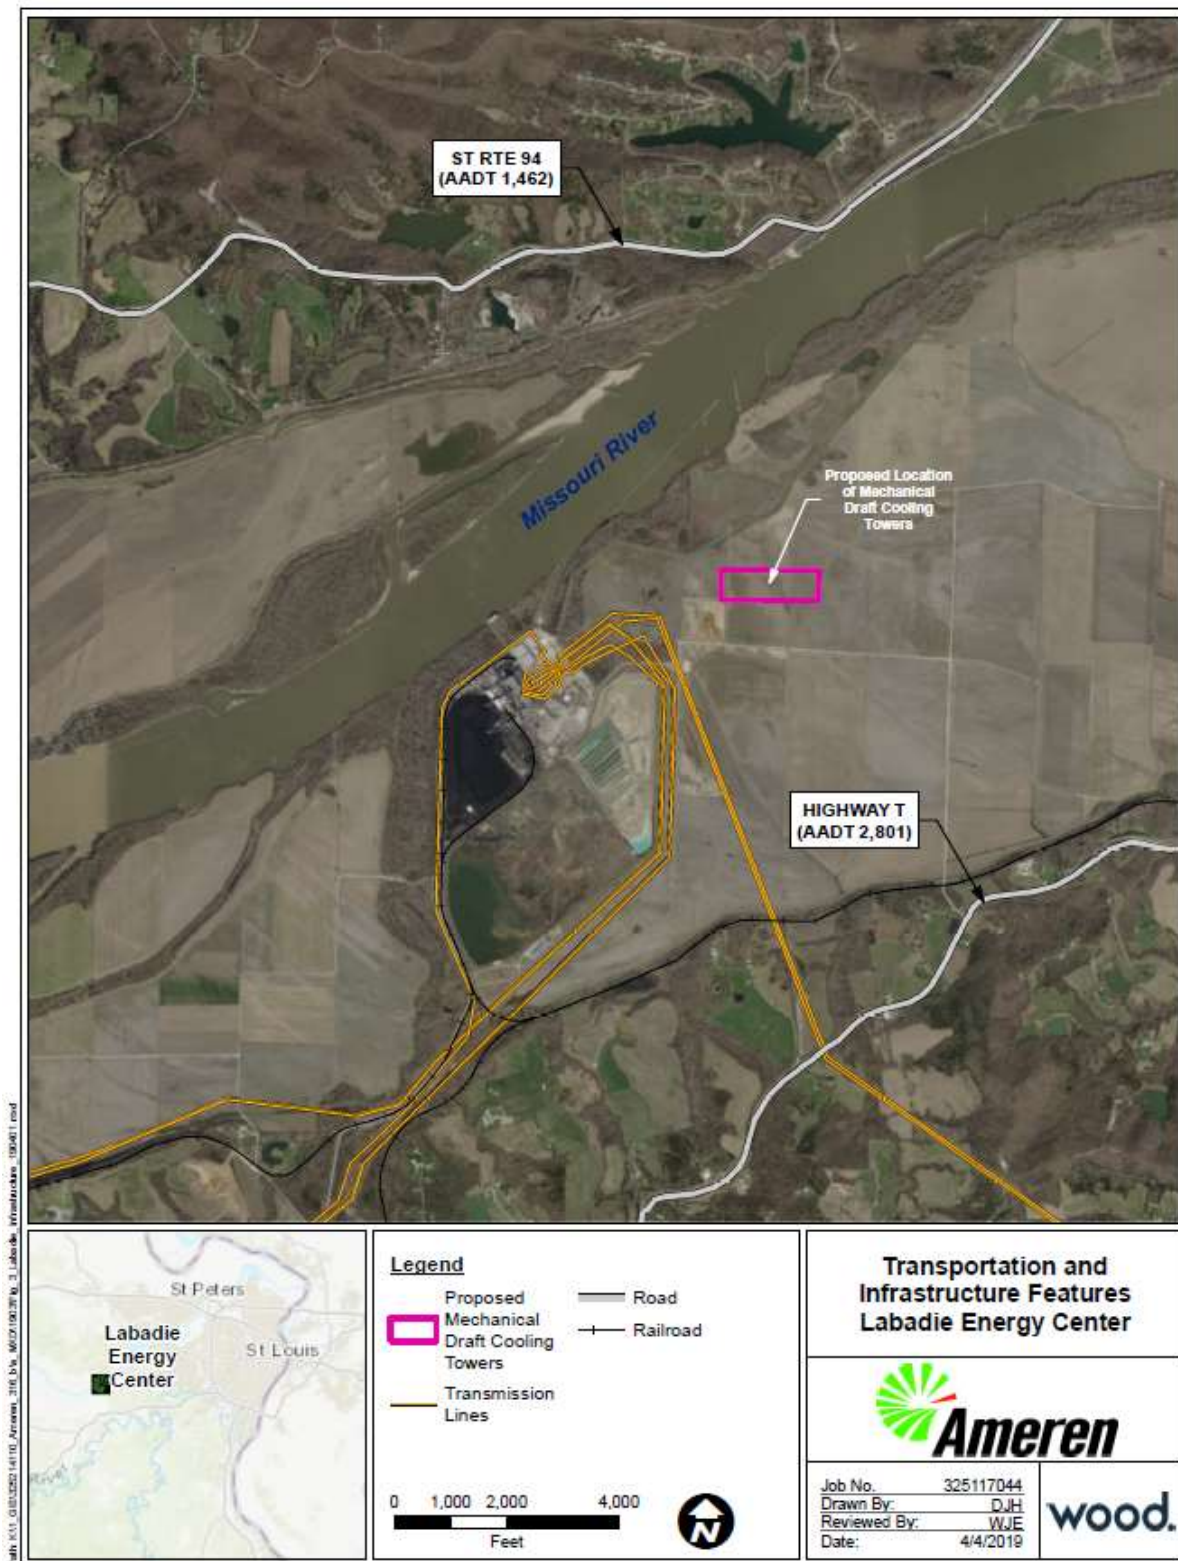

Figure 12.7. Regional Transportation Network and Surrounding Infrastructure

12.5.5 Facility Reliability

The following section provides a discussion of changes to facility reliability associated with the utilization of Mechanical Draft Cooling Towers and Fine Mesh Modified Traveling Screens at the LEC, in accordance with §122.21(r)(12)(v):

A discussion of facility reliability, including but not limited to facility availability, production of steam, impacts to production based on process unit heating or cooling, and reliability due to cooling water availability

Electric system reliability is a measure of the ability of the system to deliver power to consumers within accepted standards and in the amount desired. Reliability encompasses two concepts: adequacy and security. Adequacy implies that there are sufficient generation and transmission resources installed and available to meet projected electrical demand, taking into account scheduled and unscheduled outages of system facilities. Security implies that the system will remain intact operationally (i.e., will have sufficient available operating capacity) even after outages or other equipment failure. The degree of reliability may be measured by the frequency, duration, and magnitude of adverse effects on consumer service (U.S. Energy Information Administration, 2019).

12.5.5.1 Mechanical Draft Cooling Towers

Studies have been completed to investigate reliability impacts that could potentially result from retrofitting existing once-through facilities to closed-cycle cooling systems. The EPA conducted an analysis to evaluate energy reliability issues due to construction downtime and increased power requirements for closed-cycle auxiliary power and turbine efficiency reduction. Based on this analysis, the EPA concluded that while there may be some reliability concerns in certain locations, the effects of closed-cycle cooling on national energy reliability would be minimal (EPA, 2014).

Similarly, the modeling of five North American Electric Reliability Council reliability regions by EPRI determined that regulation-induced retirements and energy penalties would result in little risk to generation adequacy in some reliability regions, including MISO, while other regions, like the Electricity Reliability Council of Texas, Independent System Operator New England, and New York Independent System Operator, would require billions of dollars of new, unplanned generation in order to maintain adequate reserve margins. EPRI evaluated adequacy impacts for MISO, weighing load against projected capacity. Taking into account regulation-induced plant retirements and energy penalties for plants converting to closed-system cooling, MISO's projected capacity margin remained higher than the target capacity margin of 15.9% that serves as a reserve for contingencies. Additionally, in terms of security impacts for MISO, modeling indicated no major concerns associated with transmission system overload and/or voltage violations under normal operating conditions following the incorporation of the closed-cycle cooling retrofit requirement. All of the transmission system overloads were marginal and likely to be alleviated through appropriate generation re-dispatch (EPRI, 2011b).

At the facility level, the lost energy due to outages during the cooling tower retrofit, the additional auxiliary load, and turbine efficiency loss at the LEC would not be anticipated to compromise the local grid reliability because other facilities belonging to MISO would likely be able to make up for the reduction in generating capacity. However, grid reliability could be impacted in the event multiple MISO facilities have reduced generation due to cooling tower energy penalties, outages, or regulation-induced premature retirements. Coordination with MISO and other regional facilities would be necessary to ensure grid reliability impacts are minimized.

12.5.5.2 Fine Mesh Modified Traveling Screens

The installation of fine mesh modified traveling screens could allow for staged implementation of new screens for each individual generating unit, and it is expected that the unit outage necessary for conversion would be very short, if not avoidable altogether. Once installed, the operation of the modified CWIS would not result in appreciable changes to facility reliability. Therefore, no significant impacts to facility reliability are anticipated in association with the use of fine mesh modified traveling screens.

12.5.6 Water Consumption

The following section provides an estimate of changes to water consumption associated with the utilization of Mechanical Draft Cooling Towers and Fine Mesh Modified Traveling Screens at the LEC, in accordance with §122.21(r)(12)(vi)

Significant changes in consumption of water, including a facility-specific comparison of the evaporative losses of both once-through cooling and closed-cycle recirculating systems, and documentation of impacts attributable to changes in water consumption

12.5.6.1 Mechanical Draft Cooling Towers

Consumptive water loss is primarily important for facilities located on freshwater where water availability can be an issue during periods of low flow or droughts (EPRI, 2011a). In a once-through cooling water system, water consumption is negligible, as virtually all of the cooling water withdrawn is returned back to the water source. In contrast, cooling towers consume water through evaporation, as a portion of the circulating water in the cooling tower evaporates in order to cool the remainder of the water. A typical evaporation rate for mechanical draft cooling towers is 10 gpm/MW, representing 50 to 80 percent of the intake flow, depending on the COC (EPRI, 2011c).

Based on estimates provided in the BAT Analysis (Burns and McDonnell, 2018), consumptive water use from operational mechanical draft cooling towers at LEC is estimated to be between 8 and 12 gpm/MW, or up to 720 gal/megawatt-hour. At 100 percent capacity factor, this equates to a maximum of approximately 31,000 gpm of water consumption.

The proposed cooling tower design would rely on groundwater collector wells to supply all make-up water for the closed-cycle system. Groundwater in the vicinity is recharged by surface water—most

notably, the Missouri River. The mean flow of the Missouri River at LEC in recent years is 99,210 cfs, which equates to over 44 million gpm (U.S. Geological Survey, 2019). Compared to the availability of groundwater and surface water resources in the vicinity, the amount of water lost through consumptive water use, even at the maximum rate of approximately 31,000 gpm, would be negligible. Therefore, no significant impacts from water consumption are anticipated.

12.5.6.2 *Fine Mesh Modified Traveling Screens*

With the installation of fine mesh modified traveling screens, the current intake flow would be maintained, and cooling water would be returned to the Missouri River. Therefore, the use of this technology would not result in appreciable changes in water consumption.

12.5.7 Mitigation

The following section provides a discussion of potential measures to mitigate non-water quality impacts associated with the utilization of Mechanical Draft Cooling Towers and Fine Mesh Modified Traveling Screens at the LEC, in accordance with §122.21(r)(12)(vii):

A discussion of all reasonable attempts to mitigate each of these factors.

12.5.7.1 *Mechanical Draft Cooling Towers*

12.5.7.1.1 *Cooling Tower Drift*

To reduce the drift and associated PM emissions from cooling towers, drift eliminators are often incorporated into the tower design to remove as many water droplets as practical from the air stream before exiting the tower. The drift eliminators used in cooling towers are shaped materials that collect water droplets as they exit the tower. They rely on inertial separation caused by direction changes while passing through the eliminators (EPRI, 2011a). Efficient drift eliminators are commonly used in cooling towers and are frequently required for permitting. Drift eliminators were included in the cooling tower design at LEC, limiting the drift rate to approximately 0.0005 percent of the circulating water flow rate. With these drift eliminators, PM emissions associated with drift are not expected to have a significant impact on human health or the surrounding environment.

12.5.7.1.2 *Visible Plumes, Fogging, and Icing*

Plume abatement technologies are available for cooling towers where visible plumes, fogging, and icing would result in significant safety concerns and/or aesthetic viewshed degradation. Plume abatement reduces visual plumes by reducing the relative humidity of the exhaust air from the towers. Plume abatement can be done various ways, specific to each supplier. Some methods include mixing dry ambient air with the wet air, leaving the tower fill to reduce the moisture in the exhaust air. Other methods include using coils to cool a portion of the water by a dry method to reduce overall evaporation and moisture in the exhaust air.

The BAT Analysis (Burns and McDonnell, 2018) considered the use of both plume abated and non-plume abated cooling towers at the LEC. The screening analysis considered the location of the cooling towers immediately northeast of the plant. However, it was determined that at this location, non-plume abated towers would likely result in significant plume impacts at the plant, presenting safety concerns and potential excessive rime ice development on the transmission lines which would threaten plant operations. Without plume abatement, the cooling towers would need to be located farther northeast from the plant to adequately reduce these concerns.

The BAT Analysis concluded that the additional cost of plume-abated towers would be greater than the cost to relocate the towers a sufficient distance to the northeast. As the location currently proposed for the cooling towers is approximately 0.7 miles northeast of the plant and approximately 0.2 miles northeast of the closest transmission lines, plume impacts are not expected to pose significant safety or operational issues at the plant. Major roads and airports are located at a distance sufficient to disperse most fog or ice forming plumes so that safety impacts are not anticipated. Additionally, visual plume impacts are expected to be low, as the areas surrounding the LEC are predominantly rural and agricultural. For these reasons, it was determined that plume abatement for the cooling towers at the LEC would not be required.

12.5.7.1.3 Noise

Cooling tower noise consists of two primary components: one is the sound of the fans and fan drives, and the other is the sound of the water splashing down through the tower. Noise abatement technologies used primarily for reducing fan noise may include:

- ▶ Low noise fans and gear boxes,
- ▶ Fan deck barriers,
- ▶ Inlet and outlet attenuation,
- ▶ Building a larger tower to allow use of smaller hp fans and/or reduced fan tip speed, and
- ▶ Cooling tower designs that do not use fans (e.g., natural draft towers).

Noise abatement technologies used primarily for reducing water splashing noise include:

- ▶ Sound walls,
- ▶ Splash attenuation, and
- ▶ Inlet attenuation.

Various combinations of these technologies may be selected, depending on the site conditions, equipment design, noise reduction requirements, and economic considerations. The need for noise abatement is highest if towers must be located near areas with highly restrictive noise codes, such as residential areas (Tetra Tech, 2010a).

With the absence of regulatory noise limits and the significant distance between the proposed cooling towers and the closest sensitive receptors, noise impacts from a cooling tower retrofit at the LEC would be minor. Nuisance noise from the cooling towers would be limited to areas within the LEC property boundary. All sensitive receptors, including residences and recreational areas, are at enough distance that cooling tower noise would attenuate to levels below USEPA guidelines and would be consistent with background day-night noise levels for rural areas. Therefore, noise abatement technologies for the cooling towers at the LEC would not be required.

12.5.7.2 *Fine Mesh Modified Traveling Screens*

The utilization of fine mesh modified traveling screens would not result in any significant non-water quality environmental impacts or other impacts discussed above, and therefore, would not require additional mitigation measures.

12.6. SUMMARY

The non-water quality impacts of each entrainment control technology deemed feasible and practical for use at the LEC are summarized in Table 12.11.

Table 12.11. Summary of Non-Water Quality Impacts Associated with Feasible and Practical Entrainment Control Technologies at LEC

Non-Water Quality Impacts	Mechanical Draft Cooling Towers	2.0 mm Dual-Flow Fine Mesh Screen Conversion	0.5 mm Fine Mesh Screen in an Expanded CWIS
Energy Consumption	Estimated energy penalty of 38.8 MW during average summer conditions and 23.0 MW during average winter conditions.	No appreciable changes to auxiliary load or energy consumption.	Estimated additional auxiliary load of approximately 0.9 MW for new screen drives and spray pumps.
Air Pollutant Emissions	Increase in direct PM emissions of up to 20 tpy with additional regional emissions associated with replacement energy generation. Minor impacts to human health and the environment.	No reduction in generating capacity or increased emissions resulting from replacement energy generation. No impacts to human health or the environment.	Minor regional emissions associated with replacement energy generation due to reduced generating capacity. Impacts to human health and the environment would be negligible.
Noise	Maximum construction noise of 55.4 dBA and maximum operational noise of 40.4 dBA at closest sensitive receptor. Noise impacts on the surrounding community would be minor.	Maximum construction noise of 56.2 dBA at closest sensitive receptor. Operation would result in minor localized noise increases but would not result in appreciable changes at the distance of any sensitive receptors	Same impacts as 2.0 mm Dual-Flow Fine Mesh Screen Conversion
Safety	Primary concerns associated with vapor plume impacts. Current design proposes cooling towers at a sufficient distance from the plant and major roads, negating the need for plume abatement.	Continuous operation of traveling water screens would require additional operation and maintenance worker hours, increasing the potential for worker accidents and injuries.	Similar impacts as 2.0 mm Dual-Flow Fine Mesh Screen Conversion, with addition of minor increase to potential safety hazards for barges and recreational boaters due to CWIS expansion

Non-Water Quality Impacts	Mechanical Draft Cooling Towers	2.0 mm Dual-Flow Fine Mesh Screen Conversion	0.5 mm Fine Mesh Screen in an Expanded CWIS
Facility Reliability	Lost energy due to outages during retrofit, additional auxiliary load, and turbine efficiency loss would not be anticipated to compromise the local grid reliability as other facilities belonging to MISO could make up for the reduction in generating capacity.	Outage necessary for conversion would be very short, if not avoidable altogether. No significant impacts to facility reliability.	Outage necessary for conversion would be very short, if not avoidable altogether. No significant impacts to facility reliability.
Water Consumption	Maximum consumptive water use rate of approximately 31,000 gpm. Compared to the availability of groundwater and surface water resources in the vicinity, consumptive water use would be negligible.	Current intake flow would be maintained, and cooling water would be returned to the Missouri River. No appreciable changes in water consumption.	Same impacts as 2.0 mm Dual-Flow Fine Mesh Screen Conversion

13 40 CFR 122.21(R)(13) – PEER REVIEW

This section provides the names and qualifications of the peer reviewers approved by the MDNR for the § 122.21(r)(10)-(12) reports and provides a summary of the charge questions, reviewer comments, and Ameren team responses.

13.1 INTRODUCTION

Required information to meet the requirements under § 122.21(r)(13) includes the names, credentials, and qualifications of the peer reviewers (i.e. resumes), as well as documentation which provides comments by the Peer Reviews and incorporation of those comments and/or explanation of comments not accepted/addressed (i.e. charge question matrix).

13.2 PEER REVIEWERS

Three Peer Reviewers, one per discipline (biology, engineering, and economics) were selected to review the § 122.21(r)(10) Comprehensive Technical Feasibility and Cost Evaluation Study, § 122.21(r)(11) Benefits Valuation Study, and § 122.21(r)(12) Non-Water Quality and Other Impacts Assessment reports for the LEC (Table 13-1). A list of the selected Peer Reviewers, along with credentials, and qualifications were provided to the MDNR and approved prior to the initiating the review process. (Appendix 13-D.)

Dr. Lawrence W. Barnhouse of LWB Environmental Services, Inc. was selected as the Biology Peer Reviewer. Dr. Barnhouse is currently the President and Principal Scientist for LWB Environmental Services, Inc. Prior to establishing LWB Environmental Services, Dr. Barnhouse worked for 19 years for the Environmental Sciences Division of Oak Ridge National Laboratory and 3 years as a Principal Scientist for McLaren-Hart. Dr. Barnhouse has worked on many projects addressing the impacts of cooling water withdrawals on aquatic populations and communities and has completed 316(b) related research projects for the Electric Power Research Institute (EPRI). He worked with both EPRI and the Utility Water Act Group to provide comments on the proposed 316(b) rules in 2002, 2005, 2008, 2010, and 2011.

J.W. Cuchens, P.E. of Cuchens and Associates was selected as the Engineering Peer Reviewer. Mr. Cuchens served for 42 years as the Principal Engineer of cooling systems with Southern Company before establishing Cuchens and Associates for the last 3 years. With over 45 years of experience in all phases of power plant design, construction and operation with various types of generating units including nuclear, fossil, and co-generation facilities, Mr. Cuchens has been contracted to conduct multiple peer reviews of the § 122.21(r)(10) Comprehensive Technical Feasibility and Cost Evaluation Study and § 122.21(r)(12) Non-Water Quality and Other Impacts Assessment reports. The primary focus of Mr. Cuchens experience over the last 42 years has been on power plant cooling systems which consist of cooling towers, cooling ponds/lakes, steam-surface and air-cooled condensers, air removal/vacuum systems, auxiliary heat exchangers, cooling water sumps/pumps, service water equipment and related piping systems.

Dr. Frank Lupi of Michigan State University was selected as the Economics Peer Reviewer. Dr. Lupi has worked as a visiting, assistant, associate, and full professor at Michigan State University since 1998 primarily with the Department of Agricultural Economics and more recently the Department of Fish and Wildlife. In addition to his teaching responsibilities, Dr. Lupi provides outreach services including, but not limited to, economic evidence and social science expertise for natural resource damage assessments, benefits transfers, valuation of fish kills, assisting with survey and research designs and analysis, and economic effects of hydropower relicensing.

Table 13-1 Names, Affiliation, and Discipline of Peer Reviewers Selected for the LEC.

Name	Affiliation	Peer Review Discipline
Lawrence W. Barnthouse	LWB Environmental	Biology
J.W. Cuchens, P.E.	Cuchens and Associates	Engineering
Frank Lupi	Michigan State University	Economics

A full resume for each Peer Reviewer is provided in Appendices 13 A - 13 C.

13.3 CHARGE QUESTION MATRICES

A charge question matrix was developed for the biology, engineering, and economics disciplines as part of the LEC peer review process. Each matrix was provided to the associated peer reviewer who was instructed to answer the set of charge questions to guide the report review. Each set of questions included an open-ended question asking the peer reviewer to provide any additional comments/suggestions. These matrices served as the primary documentation for the LEC § 122.21(r)(13) peer review process.

Upon completion of the report reviews and responses to the charge questions, the matrices were provided to ASA and its teaming partner (Wood) cumulatively referred to herein as the “ASA Team”. The ASA Team then provided detailed responses to address each comment and/or question. Once addressed, each matrix was returned to the peer reviewers for final acknowledgement as to whether their comments were satisfactorily addressed and incorporated into the appropriate report.

The full Biology (Table 13-2), Engineering (Table 13-3), and Economics matrices (Table 13-4) have been included within this section.

Table 13-2. Engineering Peer Review Charge Question Matrix for the LEC.

Peer Reviewer Name:	Lawrence W. Barnthouse	Facility Name:	Labadie Energy Center		
Question Number	§122.21(r)(10),(11),(12)	Response	Comments (if any)	ASA Team Response	Peer Reviewer Acknowledgement
1)	Were the sample collection and processing methods (e.g., timing, location, and frequency of sampling; sampling gear used) employed to collect data used in the Benefits Valuation Study appropriate to meet the scope and requirement in §122.21(r)(11)?	Yes	The Benefits Valuation Study must rely on data provided by the §122.21(r)(9) Entrainment Characterization Study. I have examined this study and find that it fully satisfies the requirements of §122.21(r)(9) with respect to study duration, sample collection methods, sample processing methods, and annual loss calculations.	No further action needed	No further action needed
2)	Are the impingement mortality and entrainment (IM&E) reduction estimation methods used in the analyses appropriate, and are they applied correctly?	Yes	The analyses assume that under baseline conditions there is 100% mortality of entrained and impinged fish. These are reasonable assumptions, given that the traveling screens and debris removal systems were not designed to promote impingement survival and that EPA assumes 100% entrainment mortality unless site-specific data demonstrate that some eggs or larvae survive entrainment. The methods used to calculate the relationship between larval length and the probability of retention on fine-mesh screens are appropriate and have been correctly applied. The method used to estimate impingement survival for the fine-mesh screen alternative is the weakest part of the analysis. Table A-1 of the Benefits Valuation Study shows that there is very little information on impingement survival of the target species, and the range of estimated survival rates for some species and life stages is very high. The Best Professional Judgement-based survival rates listed in Table A-2 are best viewed as approximate values; uncertainty concerning these rates should be addressed through Monte Carlo analysis.	ASA has re-run the Monte Carlo analysis to include a variable for fine mesh screen survival. The results are presented in new figures at the end of the uncertainty section. The additional analysis did not affect the conclusions.	Comment adequately addressed
3)	Were the life history data and methods used to estimate equivalent loss and characterize stock dynamics of sufficient rigor for the purposes of this Study?	Yes	The life history data used to estimate equivalent fishery yield, biomass production foregone, and trophic transfer of biomass production foregone were appropriate and were well-documented. Effects of entrainment and impingement losses on stock dynamics were not addressed. As stated on page 5-6 of the Benefits Valuation Study, "...the levels of entrainment and impingement at the LEC are low relative to the reproductive potential of each of the Target Species and unlikely to induce population-level effects for any of the species involved." No studies of fish population dynamics in the Missouri River are available to test this assertion, however, a review of peer-reviewed literature adverse impacts of entrainment and impingement on fish populations (Barnthouse 2013; <i>Environmental Science & Policy</i> 31 :149-156) concluded that any such impacts are usually very small compared to impacts of harvesting.	No further action needed	No further action needed

Peer Reviewer Name:	Lawrence W. Barnthouse	Facility Name:	Labadie Energy Center		
Question Number	§122.21(r)(10),(11),(12)	Response	Comments (if any)	ASA Team Response	Peer Reviewer Acknowledgement
4)	Please discuss whether the authors identified important assumptions and uncertainties and sufficiently considered their potential impact on the results.	Yes	<p>As noted in my response to question 2, survival rates of fish eggs and larvae impinged on fine-mesh screens are highly uncertain. This uncertainty could have been addressed through Monte Carlo analysis, as were uncertainties in natural mortality rates, fishing mortality rates, and other parameters affecting the benefits estimates.</p> <p>An additional qualitative uncertainty that should be discussed is changes in fish community structure (and resultant impingement rates) during the 10 years between the impingement study and the entrainment study. When the impingement study was conducted, Asian carp were still relatively uncommon. By the time the entrainment study was conducted, Asian carp were the dominant species present in the vicinity of the station. As discussed in Section 3 of the benefits analysis, Asian carp compete with other filter feeders such as gizzard shad and may have reduced their abundance. Uncertainty resulting from fish community change cannot be quantified but should be noted in section 6.2 of the text.</p>	ASA has inserted language into the report to qualitatively address the uncertainty associated with fish community structure.	Comment adequately addressed
5)	Were the methods used to estimate the biological benefits of entrainment and impingement reductions (i.e., Equivalent Fishery Yield and Production Foregone) sufficient for the purposes of Benefits Valuation? Are the methods used of sufficient rigor to support an entrainment best technology available (BTA) assessment for this facility?	Yes	The methods used to estimate the biological benefits of the entrainment reduction technologies addressed in the report have been used by EPA in the agency's own benefits analyses and are well-documented in EPRI reports. I believe they are the best available methods for addressing biological benefits of entrainment and impingement reductions.	No further action needed	No further action needed
6)	Does the feasibility evaluation in 122.21(r)(10) appropriately reflect biological considerations of biological effectiveness for fine mesh size based on aquatic organisms intended to be protected by the fine-mesh retrofit?	Yes	The feasibility evaluation provides an excellent discussion of the biological effectiveness of fine-mesh screens. Issues of the relationship between mesh size and larval retention are properly addressed. The effect of through-screen velocity on the survival of retained larvae is adequately addressed. The evaluation persuasively shows that the 0.5 mm mesh screen would be more effective than the 1.0 mm or 2.0 mm screens at retaining the species and lengths of larvae entrained at the Labadie station.	No further action needed	No further action needed
7)	Does the Peer Reviewer have additional comments and/or input regarding whether the biological and estimated losses and benefits valuation sections of 122.21(r)(11) are consistent with and meet the requirements of the Rule? If so, please provide a narrative.	Yes	The documents provided to me are very well-organized and the conclusions are well-supported by the data. I provided a few minor comments and suggestions for change in response to questions 2 and 4, however, my overall conclusion is that the biological benefits analyses included in the 122.21(r)(11) Benefits Valuation Study fully satisfy the requirements of the Rule.	No further action needed	No further action needed

Table 13-3. Engineering Peer Review Charge Question Matrix for the LEC.

Peer Reviewer Name:	J. W. Cuchens, P.E.	Facility Name:	Labadie Energy Center		
Question Number	§122.21(r)(10),(12)	Response	Comments (if any)	ASA Team Response	Peer Reviewer Acknowledgement
1)	Does the 122.21(r)(10) report provide a site-specific evaluation of closed-cycle cooling, to the extent required by the Rule, and is it of sufficient rigor to support an entrainment best technology available (BTA) assessment for this station? If not, describe the nature of evaluation needed.	<input checked="" type="radio"/> Y/ <input type="radio"/> N	The report provides an accurate site specific evaluation of closed cycle cooling system including consideration of various cooling tower technologies. The evaluation of closed cycle cooling included a thorough examination of site specific considerations (space, costs, interferences, performance, etc.) to provide an assessment of CCC system as a valid candidate BTA.	No further action needed	Agreed
2)	Does the 122.21(r)(10) report provide a site-specific evaluation of fine-mesh screens, to the extent required by the Rule, and is it of sufficient rigor to support an entrainment best technology available (BTA) assessment for this station?	<input checked="" type="radio"/> Y/ <input type="radio"/> N	The report provides a site specific evaluation of fine mesh screening systems including consideration of various screen technologies, screen mesh sizes, and screen intake velocities. The evaluation of closed cycle cooling included a thorough examination of site specific details (fine mesh technologies, retrofit requirements, limited space, permitting, flows velocities, costs, etc.) to provide an accurate assessment of fine mesh screens options which would be a candidate BTA.	No further action needed	Agreed
3)	Please discuss whether important assumptions and uncertainties were identified and their potential impact on results were sufficiently considered in the analysis.	<input checked="" type="radio"/> Y/ <input type="radio"/> N	Assumptions were identified along with uncertainties.as appropriate. The assumption of cooling pond capacity was considered prudent for conservative use. Sizing TWS for a zero blockage is obviously impractical but the rule removed the blockage factor requirement. The engineering level of detail was considered more than sufficient to identify and address some uncertainties and/or potential impacts on implementation. Cost assumptions & discount factors were applied within the bounds of accuracies required/reflected.	No further action needed	Agreed
4)	Are the compliance cost approaches in 122.21(r)(10) appropriate for what's required by the Rule?	<input checked="" type="radio"/> Y/ <input type="radio"/> N	Compliance costs (net present value after tax) were developed as required by the rule for technologies evaluated including design/construction, ad-min, permitting, outage time, and O&M costs. Compliance costs developed by B&V and Wood were reviewed for inclusion of major cost components as appropriate	No further action needed	Agreed

Peer Reviewer Name:	J. W. Cuchens, P.E.	Facility Name:	Labadie Energy Center		
Question Number	§122.21(r)(10),(12)	Response	Comments (if any)	ASA Team Response	Peer Reviewer Acknowledgement
5)	Did the 122.21(r)(12) report assess all applicable closed-cycle cooling and fine-mesh impacts required by the Rule? If not, list the impacts that need further consideration and nature of additional consideration. Were all reasonable attempts to mitigate each of these impacts discussed? If not, list impacts that need additional mitigation measures and nature of those mitigation measures.	Y/N	The report included assessment of CCS alternative technologies as required by the rule including but not limited to use of natural draft cooling towers, mechanical draft cooling towers, hybrid designs, and various multi-cell arrangements. The report also included assessment of alternative screen technologies as required by the rule including but not limited to fine mesh single/dual flow TWS, fine mesh wedge wire screens, retrofit existing system with fine mesh screens. Each of the alternatives considered required identifying impacts and potential mitigation of impacts (and CCS with use of natural draft cooling towers, mechanical draft cooling towers, hybrid designs, and various multi-cell arrangements	No further action needed	Agreed
6)	Does the alternate water source evaluation meet the requirements of the Rule? If not, describe why not.	Y/N	The report identified necessary water requirements for each technology considered and the potential sources of various alternative water supplies. The report concluded that insufficient alternative water sources are unavailable to meet the minimum requirements and consequently satisfied the requirements of the rule to have considered such. The report reflected a thorough examination of alternate water resources within a wide boundary from the plant site.	No further action needed	Agreed
7)	Does the Peer Reviewer have additional comments and/or input regarding whether the engineering sections of 122.21(r)(10) and (12) are consistent with and meet the requirements of the Rule? If so, please provide a narrative.	Y/N	See Comments Included Below		

Table 13-4. Economics Peer Review Charge Question Matrix for the LEC.

Peer Reviewer Name:	Frank Lupi	Facility Name:	Labadie Energy Center		
Question Number	§122.21(r)(10),(11),(12)	Response	Comments (if any)	ASA Team Response	Peer Reviewer Acknowledgement
1)	Are the owner/engineering costs to the Labadie Energy Center (LEC) of entrainment reduction technologies presented in sufficient detail to allow estimation of the social costs associated with the increased cost to the LEC?	Yes		No further action needed.	OK
2)	Were the social costs presented in these reports for each of the proposed entrainment reduction technologies developed in accordance with procedures in Environmental Protection Agency's (EPA's) Economic Analysis for the Final Section 316(b) Existing Facilities Rule, May 2014? If not, are methods consistent with applicable social cost evaluation methods?	Yes		No further action needed.	K
3)	Does the biology evaluation in 122.21(r)(11) provide sufficient input to perform the social benefits evaluation in 122.21(r)(11)?	Yes	The approach is used in many 316b evaluations and provides sufficient information for social benefits evaluation, but since I am not a biologist, I cannot attest to the parameter assumptions that were used in that analysis.	Parameter assumptions were reviewed by the biology peer reviewer. No further action needed	OK
4)	Were the social benefits presented in these reports for each of the proposed entrainment reduction technologies developed in accordance with procedures in EPA's Benefits Analysis for the Final Section 316(b) Existing Facilities Rule, May 2014? If not, are the methods consistent with standard resource economics evaluation methods? If not, provide comments or questions.	Yes		No further action needed.	OK
5)	If there are any key social benefits that should be included in the 122.21(r)(11) section, that have been left out? If so, please list them. If those benefits were included in the monetization, would the overall assessment of benefits change materially?	No	No key benefits were omitted, and given the biological changes, any unquantified social benefits are highly unlikely to materially change the assessment.	No further action needed.	OK
6)	Section 125.98(f) of the Final Rule indicates that quantitative and qualitative social benefits and costs of available entrainment reduction technologies may be considered in making a Best Technology Available (BTA) determination when such information (on both benefits and costs) has been developed with sufficient rigor. Are the social costs and benefits presented in these §122.21(r)(10)-(12) reports evaluated with sufficient rigor to be used in the BTA determination? If not, provide comments or questions.	Yes		No further action needed.	OK
7)	Were the data inputs and process used to estimate the	Yes	My additional minor comments speak to this point in more detail,		

Peer Reviewer Name:	Frank Lupi	Facility Name:	Labadie Energy Center		
Question Number	§122.21(r)(10),(11),(12)	Response	Comments (if any)	ASA Team Response	Peer Reviewer Acknowledgement
	economic value of direct and indirect use benefits scientifically defensible and sufficient for the purposes of Benefits Valuation?		but addressing those comments would be highly unlikely to materially change the assessment.	No further action needed.	OK
8)	Were non-use benefits qualitatively addressed in a scientifically defensible manner sufficient for the purposes of Benefits Valuation?	Yes	I do not endorse all the statements in the report about non-use values, but I do agree with the study assertion that for the projected changes in fish biomass, non-use values are likely “very small or non-existent.”	No further action needed.	OK
9)	Were the data inputs and process used to estimate the life-time economic benefits of each alternative generally consistent with Industry Practices and sufficient for the purposes of Benefits Valuation?	Yes		No further action needed.	OK
10)	Does the Peer Reviewer have additional comments and/or input regarding whether the economic analyses of 122.21(r)(10), (11), and (12) are consistent with and meet the requirements of the Rule? If so, please provide a narrative.	Yes	Additional minor comments submitted as an attachment.	No further action needed.	OK
			The following additional comments apply to the r(10) report		
11)			In table 3-2, the 5.94% cost of capital (discount rate) seems reasonable, but it is not clear what the reference for supporting data is (Ameren Economics)	5.94% is based on Ameren’s own historical cost of capital.	OK
12)			Why do the numbers for discount rate and escalation differ in table 3-2 from those in 6-1? The numbers in the B&M report (in appendix table on page 113 of the r10 PDF document) match those of table 3-2.	The value of 6.00% reported in Table 6-1 of r10 for Discount Rate is a typo. Life-cycle cost for screen technologies in section 6 of r10 were calculated with a discount rate of 5.94%. The same percentage used in B&M 2018. The difference between the Capital Cost Escalation Rate is likely attributed to the reliance on the Handy-Whitman Index and the time lapse between B&M calculations and Wood’s calculations. All other values are consistent. The final r10 report will correct the error associated with the Discount Rate.	OK
13)			Is the use of different project contingency rates across technologies intentional? Specifically, many places mention a 30% contingency (e.g., Table 6-2 and the Black & Veatch calculations), but some use 15% (e.g., Table 6-5 for the 0.5 mm mesh). The various contingencies for cooling towers in the Burns and McDonnell calculations (PDF pages 82-83, B&M	The difference between the contingency values is attributed to the firm providing the estimate. B&V use 30%, B&M used 20% and Wood used 15%. Wood cited the dollar values calculated by B&M	OK, as it be highly unlikely to materially change the assessment.

Peer Reviewer Name:	Frank Lupi	Facility Name:	Labadie Energy Center		
Question Number	§122.21(r)(10),(11),(12)	Response	Comments (if any)	ASA Team Response	Peer Reviewer Acknowledgement
			pages 4-4 to 4-5) differ from the contingencies for both screen mesh sizes. I was not clear if this is the result of different firms performing the analyses or due to intended differences by technologies.	and B&V without alteration. Changing the values for consistency was likely to lead to confusion for reviewers. No further action needed.	
14)			In tables presenting annual values for social costs, the annual values are presented as the net present values divided by 30. This approach is not how one annualizes values in economics or finance because it ignores the interest rate when converting between the present values (PV) and annual values (AV). That is, the AV for a PV=\$X would be the fixed amount every year for N years that at r% would give a PV=\$X. It is not PV/N unless the interest rate is 0%. I am aware that this approach has been used in other 316b studies; however, this approach for converting social costs to annual values differs from the approach for social benefits in r(11) which appears to use the typical approach from finance and economics.	To keep social cost estimates consistent with the benefit estimates detailed in the r(11) report, annualized social costs were recalculated utilizing the equation: $Annualized\ cost = \frac{r(NPV)}{1-(1+r)^{-n}}$ Where r is the discount rate and n is the number of years that the analysis is conducted over. In the r(10) report, Table 3-4 (page 18), Table 6-4 (page 35) and Table 6-7 (page 38) will all be updated with the revised annualized cost presented in Table 1 of the Social Cost Report.	OK
15)			Table 3 of the Veritas appendix (PDF p200) presents possible incidence of price increases by household incomes. It does so by using a fixed average amount of energy consumption applied to all household income groups. However, there are many studies that show electricity demand responds to income and that price elasticities can differ by income. The implication is that price increases may disproportionately affect the poor, but not to the extent of the example.	The text is intended to provide an illustrative example of how rate increases affect consumers' wellbeing and translate into social costs. It is not a depiction of the process we use to convert the compliance costs into social costs. The text describing that process is provided in the first paragraph following Table 2. Specifically, the text describes that, "To develop the electricity price increases, the design, construction, and installation costs are allocated over the specified construction and installation time-periods presented in Table 2. Operation and maintenance costs are then added for each year the technology is operational, and the future stream of those costs are discounted by 3 and 7 percent to develop the	OK

Peer Reviewer Name:	Frank Lupi	Facility Name:	Labadie Energy Center		
Question Number	§122.21(r)(10),(11),(12)	Response	Comments (if any)	ASA Team Response	Peer Reviewer Acknowledgement
				present value estimate for each discount rate.” This approach is used to approximate the social costs associated with the compliance costs being passed on to rate payers.	
16)			Section 2.1 of the Veritas appendix (PDF p201, including footnote 2) argues that consumers equate total willingness to pay across goods. However, theory only suggests that the last dollar spent on each good generates the same increment in value, not all dollars spent. Thus, one cannot infer surplus a good by knowing it for another. The text mentions that estimates from fishing studies suggest the ratio of total willingness to pay versus cost is 1.4, though, as mentioned above, this tells us nothing about surplus value from electricity use. Further, it is unclear if this 1.4 factor was used at all in the social cost computations.	The text is intended to provide an illustrative example of how rate increases affect consumers’ wellbeing and translate into social costs. It is not a depiction of the process we use to convert the compliance costs into social costs. The text describing that process is provided in the first paragraph following Table 2. Specifically, the text describes that, “To develop the electricity price increases, the design, construction, and installation costs are allocated over the specified construction and installation time-periods presented in Table 2. Operation and maintenance costs are then added for each year the technology is operational, and the future stream of those costs are discounted by 3 and 7 percent to develop the present value estimate for each discount rate.” This approach is used to approximate the social costs associated with the compliance costs being passed on to rate payers. Additionally, the reference of a willingness to pay value of 40% more than expenditures in the illustrative example has been removed.	OK
17)			Minor typo: Footnote a of tables 3-4, 6-4 and 6-7 should refer to table 1 of Veritas 2019.	Wood will correct this error in the final report. No further action needed.	OK
18)			Minor typo: On page P16 (PDF p23), the third to last sentence	Wood will correct this error in the	OK

Peer Reviewer Name:	Frank Lupi	Facility Name:	Labadie Energy Center		
Question Number	§122.21(r)(10),(11),(12)	Response	Comments (if any)	ASA Team Response	Peer Reviewer Acknowledgement
			repeats “life-cycle costs”.	final report. No further action needed.	
			The following additional comments apply to the r(11) report		
19)			The standard in economics for valuing recreational fishery benefits is to use non-market valuation methods because there is no primary market for recreational fishing. As such, the sentence on page 5-3 (PDF p36) makes little sense. “Unfortunately, economic value of increased recreational use of the resource is not directly reflected in the primary market – i.e., the market for recreational fishing.” That said, the non-market valuation method employed is adequate.	We will delete “...-i.e., the market for recreational fishing”.	OK
20)			Regarding what to do about recreational catch and release fishing, the source material for the recreational fish value data is EPA chapter A5 (2006). There EPA discussed values for recreationally caught fish, and in that chapter EPA makes no distinction between harvested or released fish in the discussion of the underlying data for the meta-analyses of the value to recreational anglers for catching an additional fish. Inspection of several of the underlying studies shows they did make any distinction either. Thus, the EPA meta-analysis results are for the value of a caught fish, regardless of whether it is released. Thus, I see no basis for assigning released fish a lower value than other fish. That would mean that in the equation on page 5-5 (PDF p38), RFHF =1 not 0.5. This adjustment would not likely to change any overall conclusions regarding the disproportionately large costs compared to benefits.	Our approach was based on the understanding that many of the studies upon which EPA values are based were conducted a number of years ago when catch-and-release were less common. Further, we do not believe that anglers would value a fishery for panfish where they could not keep some of the catch. After all, the motivation for fishing for these species is primarily as food not sport. They would be analogous to meat category in the paper by Carter and Liese (2012) The Economic Value of Catching and Keeping or Releasing Saltwater Sport Fish in the Southeast USA North American Journal of Fisheries Management 32:613–625, which found released meat fish had much lower value than kept fish. That said, we agree that conclusions won't change regardless of what assumption is made.	Perhaps, but the implications of the lower catch and release values should still be implicit in the EPA meta-analysis since, even if it is growing for this species, catch and release is not an altogether new phenomenon. Regardless, any adjustment is unlikely to materially change the assessment.
21)			Again, for released fish, table t-2 (p195) of MDOC (2011) shows catch and harvest results for a segment of the river that appears to be more specific to the LEC region of entrainment. It shows release to harvest ratios are more like 3 to 1 for channel catfish relative the numbers for the whole river, and the release to harvest ratio is also larger in this segment for freshwater drum.	The values we used were from Table 8 reflecting the entire lower river. We chose those from a smaller geographic area because of larger sample size coupled with the fact that individuals not entrained or	OK

			Accounting for this difference would not likely to change any overall conclusions regarding the disproportionally large costs compared to benefits.	impinged at the LEC could grow up to be caught in other river reaches. That said, we agree that any differences would not like to change any overall conclusions.	
22)			The MDOC table t-2 (MDOC 2011) also shows that there is a non-trivial amount of sturgeon harvested in this stretch that while sturgeon catch is only 10% of channel catfish, they are likely more valuable to anglers (e.g., EPA 2014). That said, any adjustment for this would likely not be large enough to change the relative magnitudes of the costs and benefits.	We agree that sturgeon are more valuable than catfish. However, sturgeon feed on plant material and detritus. Hence, they would not be appropriate as an equivalent predator.	OK
23)			In the uncertainty analysis, it is suggested that values for fish will be lower in Missouri River due to consumption advisories. Several recreationally important species in some of the studies underlying the EPA meta-analyses were also subject to consumption advisories, so this effect is already partially reflected in the estimates of fish values that are being transferred to the Missouri River. This adjustment would not change any overall conclusions regarding the disproportionally large costs compared to benefits.	Agree that the values are partially reflected in the EPA values. However, the degree to which they are reflected is uncertain and, in our opinion, likely small.	OK

Characterization Data**

Supplemental Data Tables

Table 4 A-1 Species Belonging to Carp and Minnow Family Groups Identified by Distinct Morphological Characters (Fuiman et al. 1983) Known to Occur near the LEC.

Minnow Family Group	Distinctive Larval Character	Fish Common Name	
Group 1	High preanal length	Goldfish Common carp	Grass carp
Group 2	Flattened eye	Speckled chub Silver chub Bluntnose minnow Shoal chub ¹	Sand shiner Suckermouth minnow Bullhead minnow
Group 3	High preanal myomere number (>25)	Central stoneroller Striped shiner	Creek chub Common shiner
Group 4	Midventral stripe	Golden shiner Emerald shiner Mimic shiner	Rosyface shiner Silverband shiner Fathead minnow
Group 5	Scattered breast	Bigmouth shiner	
Group 6	Outlined gut	River shiner Spotfin shiner	Red shiner

¹ The shoal chub was elevated to full species status from the speckled chub species-complex through morphological studies by Eisenhour (1999, 2004) and genetic studies by Underwood et al. (2003). Henceforth, all specimens formerly identified as speckled chub are now identified as shoal chub.

Appendix 9 A

40 CFR 122.21(r)(9) – Entrainment Characterization Study

Supplemental Data Tables

Table 9 A-1 List of Fish Taxa Identified Within the Lower Missouri River in the Vicinity of the Labadie Energy Center, 1974-2018.

Family	Scientific Name	Common Name
Acipenseridae-sturgeons	<i>Acipenser fulvescens</i>	Lake sturgeon
	<i>Scaphirhynchus albus</i>	Pallid sturgeon
	<i>Scaphirhynchus platyrhynchus</i>	Shovelnose sturgeon
	<i>S. albus</i> × <i>S. platyrhynchus</i>	Pallid sturgeon × shovelnose sturgeon
Amiidae-bowfins	<i>Amia calva</i>	Bowfin
Anguillidae-freshwater eels	<i>Anguilla rostrata</i>	American eel
Atherinopsidae-New World silversides	<i>Labidesthes sicculus</i>	Brook silverside
Catostomidae-suckers	<i>Carpionodes carpio</i>	River carpsucker
	<i>Carpionodes cyprinus</i>	Quillback
	<i>Carpionodes velifer</i>	Highfin carpsucker
	<i>Catostomus commersonii</i>	White sucker
	<i>Cycleptus elongatus</i>	Blue sucker
	<i>Hypentelium nigricans</i>	Northern hog sucker
	<i>Ictiobus bubalus</i>	Smallmouth buffalo
	<i>Ictiobus cyprinellus</i>	Bigmouth buffalo
	<i>Ictiobus niger</i>	Black buffalo
	<i>Minytrema melanops</i>	Spotted sucker
	<i>Moxostoma carinatum</i>	River redhorse
	<i>Moxostoma erythrurum</i>	Golden redhorse
	<i>Moxostoma macrolepidotum</i>	Shorthead redhorse
Centrarchidae-sunfishes	<i>Ambloplites rupestris</i>	Rock bass
	<i>Lepomis cyanellus</i>	Green sunfish
	<i>Lepomis gulosus</i>	Warmouth
	<i>Lepomis humilis</i>	Orangespotted sunfish
	<i>Lepomis macrochirus</i>	Bluegill
	<i>Lepomis megalotis</i>	Longear sunfish
	<i>Lepomis punctatus</i>	Spotted sunfish
	<i>Micropterus dolomieu</i>	Smallmouth bass
	<i>Micropterus punctulatus</i>	Spotted bass
	<i>Micropterus salmoides</i>	Largemouth bass
	<i>Pomoxis annularis</i>	White crappie
	<i>Pomoxis nigromaculatus</i>	Black crappie
Clupeidae-herrings	<i>Alosa chrysochloris</i>	Skipjack herring
	<i>Dorosoma cepedianum</i>	Gizzard shad
Cyprinidae-carps and minnows	<i>Campostoma anomalum</i>	Central stoneroller
	<i>Campostoma oligolepis</i>	Largescale stoneroller
	<i>Carassius auratus</i>	Goldfish
	<i>Ctenopharyngodon cf. idella</i>	Grass carp
	<i>Cyprinella lutrensis</i>	Red shiner
	<i>Cyprinella spiloptera</i>	Spotfin shiner
	<i>Cyprinus carpio</i>	Common carp
	<i>Erimystax x-punctatus</i>	Gravel chub
	<i>Hybognathus argyritis</i>	Western silvery minnow
	<i>Hybognathus placitus</i>	Plains minnow
	<i>Hypophthalmichthys molitrix</i>	Silver carp

Family	Scientific Name	Common Name
Cyprinidae-carps and minnows	<i>Hypophthalmichthys nobilis</i>	Bighead carp
	<i>Luxilus chrysocephalus</i>	Striped shiner
	<i>Luxilus cornutus</i>	Common shiner
	<i>Lythrurus umbratilis</i>	Redfin shiner
	<i>Macrhybopsis aestivalis</i>	Speckled chub
	<i>Macrhybopsis gelida</i>	Sturgeon chub
	<i>Macrhybopsis hyostoma</i>	Shoal chub
	<i>Macrhybopsis meeki</i>	Sicklefin chub
	<i>Macrhybopsis storeriana</i>	Silver chub
	<i>Notemigonus crysoleucas</i>	Golden shiner
	<i>Notropis atherinoides</i>	Emerald shiner
	<i>Notropis blennioides</i>	River shiner
	<i>Notropis boops</i>	Bigeye shiner
	<i>Notropis burchanani</i>	Ghost shiner
	<i>Notropis dorsalis</i>	Bigmouth shiner
	<i>Notropis rubellus</i>	Rosyface shiner
	<i>Notropis shumardi</i>	Silverband shiner
	<i>Notropis stramineus</i>	Sand shiner
	<i>Notropis volucellus</i>	Mimic shiner
	<i>Notropis wickliffi</i>	Channel shiner
	<i>Phenacobius mirabilis</i>	Suckermouth minnow
	<i>Pimephales notatus</i>	Bluntnose minnow
	<i>Pimephales promelas</i>	Fathead minnow
	<i>Pimephales vigilax</i>	Bullhead minnow
	<i>Platygobio gracilis</i>	Flathead chub
	<i>Semotilus atromaculatus</i>	Creek chub
Esocidae-pikes and	<i>Esox lucius</i>	Northern pike
Fundulidae-topminnows	<i>Fundulus olivaceus</i>	Blackspotted topminnow
	<i>Fundulus zebrinus</i>	Plains killifish
Hiodontidae-mooneyes	<i>Hiodon alosoides</i>	Goldeye
	<i>Hiodon tergisus</i>	Mooneye
Ictaluridae-North American catfishes	<i>Ameiurus melas</i>	Black bullhead
	<i>Ameiurus natalis</i>	Yellow bullhead
Ictaluridae-North American catfishes	<i>Ictalurus furcatus</i>	Blue catfish
	<i>Ictalurus punctatus</i>	Channel catfish
	<i>Noturus flavus</i>	Stonecat
	<i>Noturus gyrinus</i>	Tadpole madtom
	<i>Noturus nocturnus</i>	Freckled madtom
	<i>Pylodictis olivaris</i>	Flathead catfish
Lepisosteidae-gars	<i>Lepisosteus oculatus</i>	Spotted gar
	<i>Lepisosteus osseus</i>	Longnose gar
	<i>Lepisosteus platostomus</i>	Shortnose gar
Moronidae-temperate basses	<i>Morone chrysops</i>	White bass
	<i>Morone mississippiensis</i>	Yellow bass
	<i>Morone saxatilis</i>	Striped bass
	<i>M. saxatilis</i> × <i>M. chrysops</i>	Striped bass × white bass
Osmeridae-smelts	<i>Osmerus mordax</i>	Rainbow smelt
Percidae-perches	<i>Etheostoma nigrum</i>	Johnny darter
	<i>Etheostoma tetrazonum</i>	Missouri saddled darter
	<i>Etheostoma zonale</i>	Banded darter

Family	Scientific Name	Common Name
	<i>Percina caprodes</i>	Logperch
	<i>Percina maculata</i>	Blackside darter
	<i>Percina phoxocephala</i>	Slenderhead darter
	<i>Percina shumardi</i>	River darter
Percidae-perches	<i>Sander canadensis</i>	Sauger
	<i>Sander vitreus</i>	Walleye
	<i>S. canadensis</i> × <i>S. vitreus</i>	Saugeye (Sauger × walleye)
Petromyzontidae-lampreys	<i>Ichthyomyzon castaneus</i>	Chestnut lamprey
	<i>Ichthyomyzon unicuspis</i>	Silver lamprey
Poeciliidae-liverbearers	<i>Gambusia affinis</i>	Western mosquitofish
Polyodontidae-paddlefishes	<i>Polyodon spathula</i>	Paddlefish
Sciaenidae-drums and croakers	<i>Aplodinotus grunniens</i>	Freshwater drum

Table 9 A-2 Sampling Interval Density, Daytime and Nighttime Mean Density, and Event Mean Density of Each Taxon and Development Stage Collected During 2015 and 2016 Entrainment Sampling Conducted at the LEC.

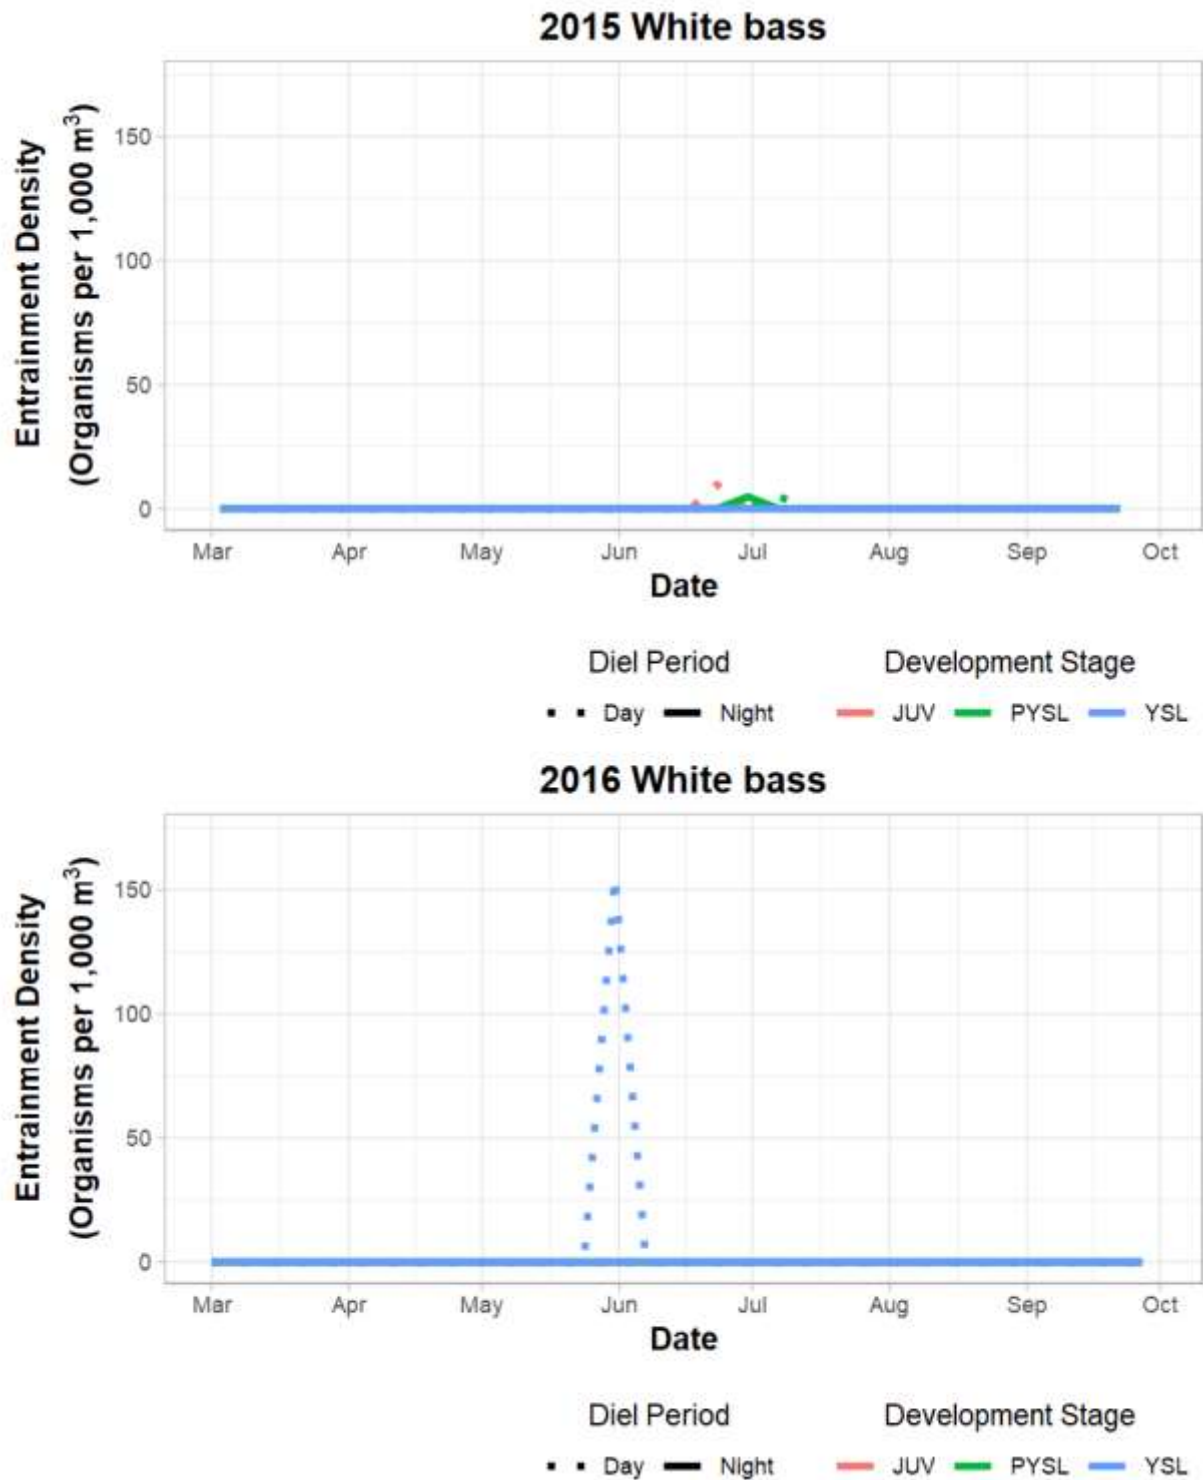

Figure 9 C-41 Mean Daytime and Nighttime Entrainment of White Bass by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

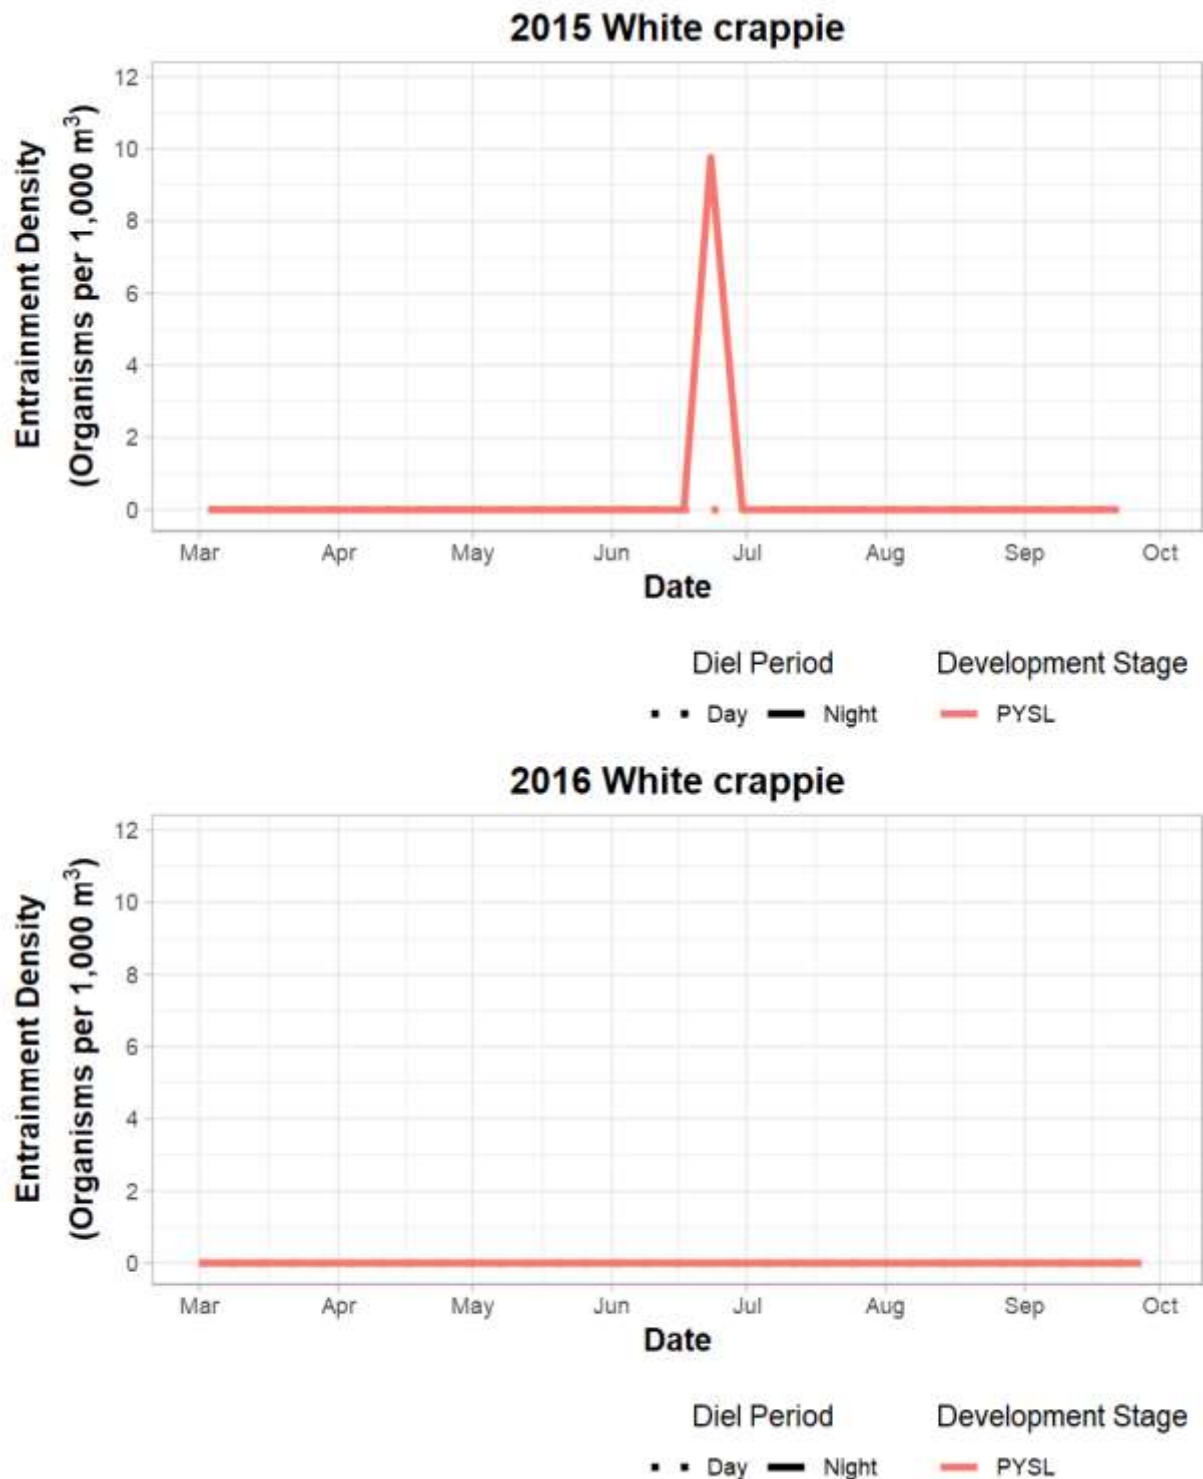

Figure 9 C-42 Mean Daytime and Nighttime Entrainment of White Crappie by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

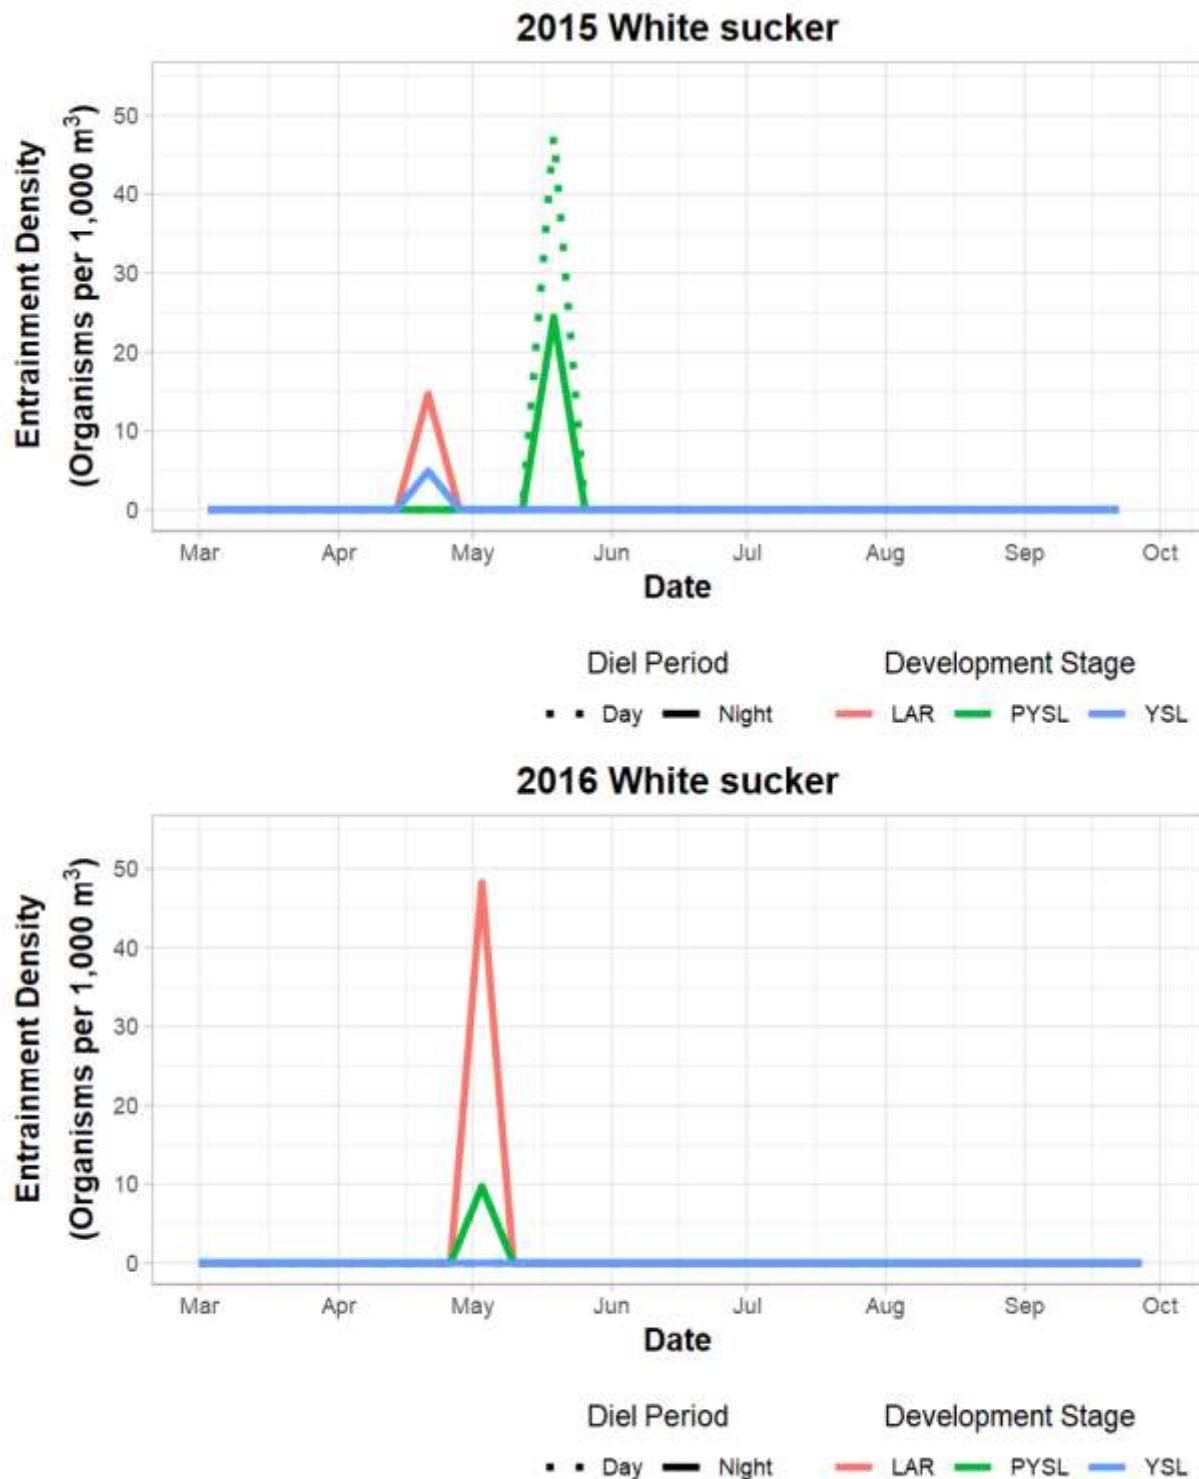

Figure 9 C-43 Mean Daytime and Nighttime Entrainment of White Sucker by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

Appendix 9 D

40 CFR 122.21(r)(9) – Entrainment Characterization Study

Length Histograms of All Taxa and Development Stages Entrained at Labadie Energy Center, 2015 and 2016

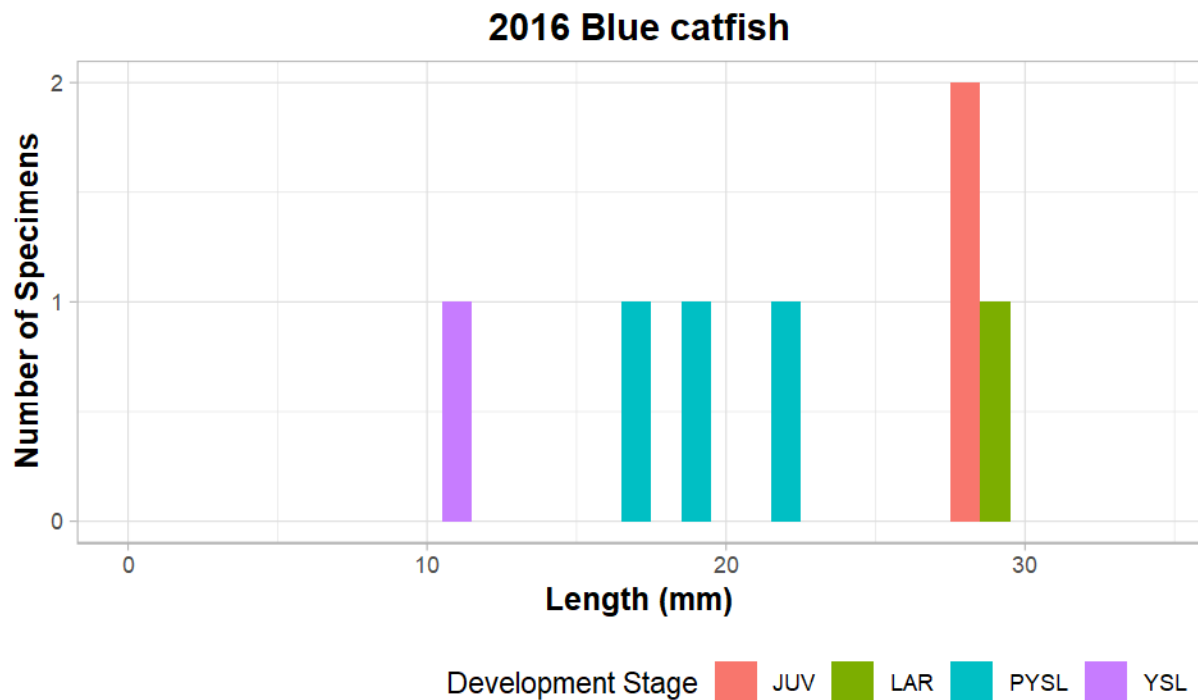

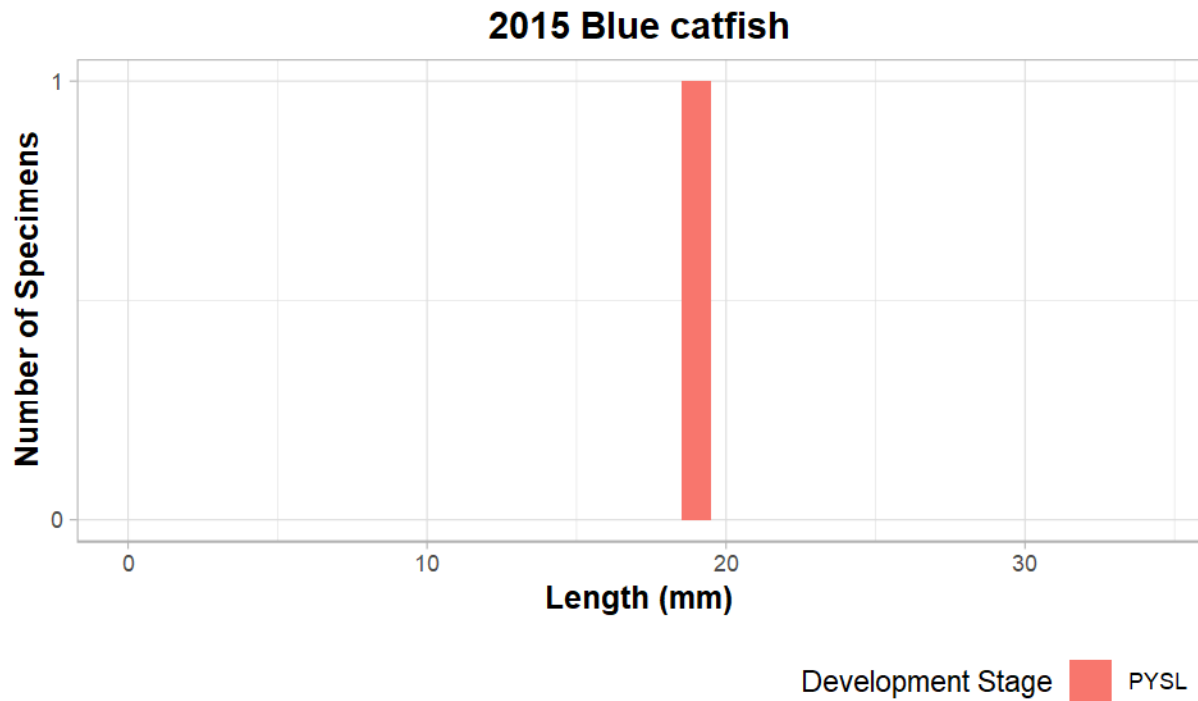

Figure 9 D-1 Length Histogram of Entrained Blue Catfish by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

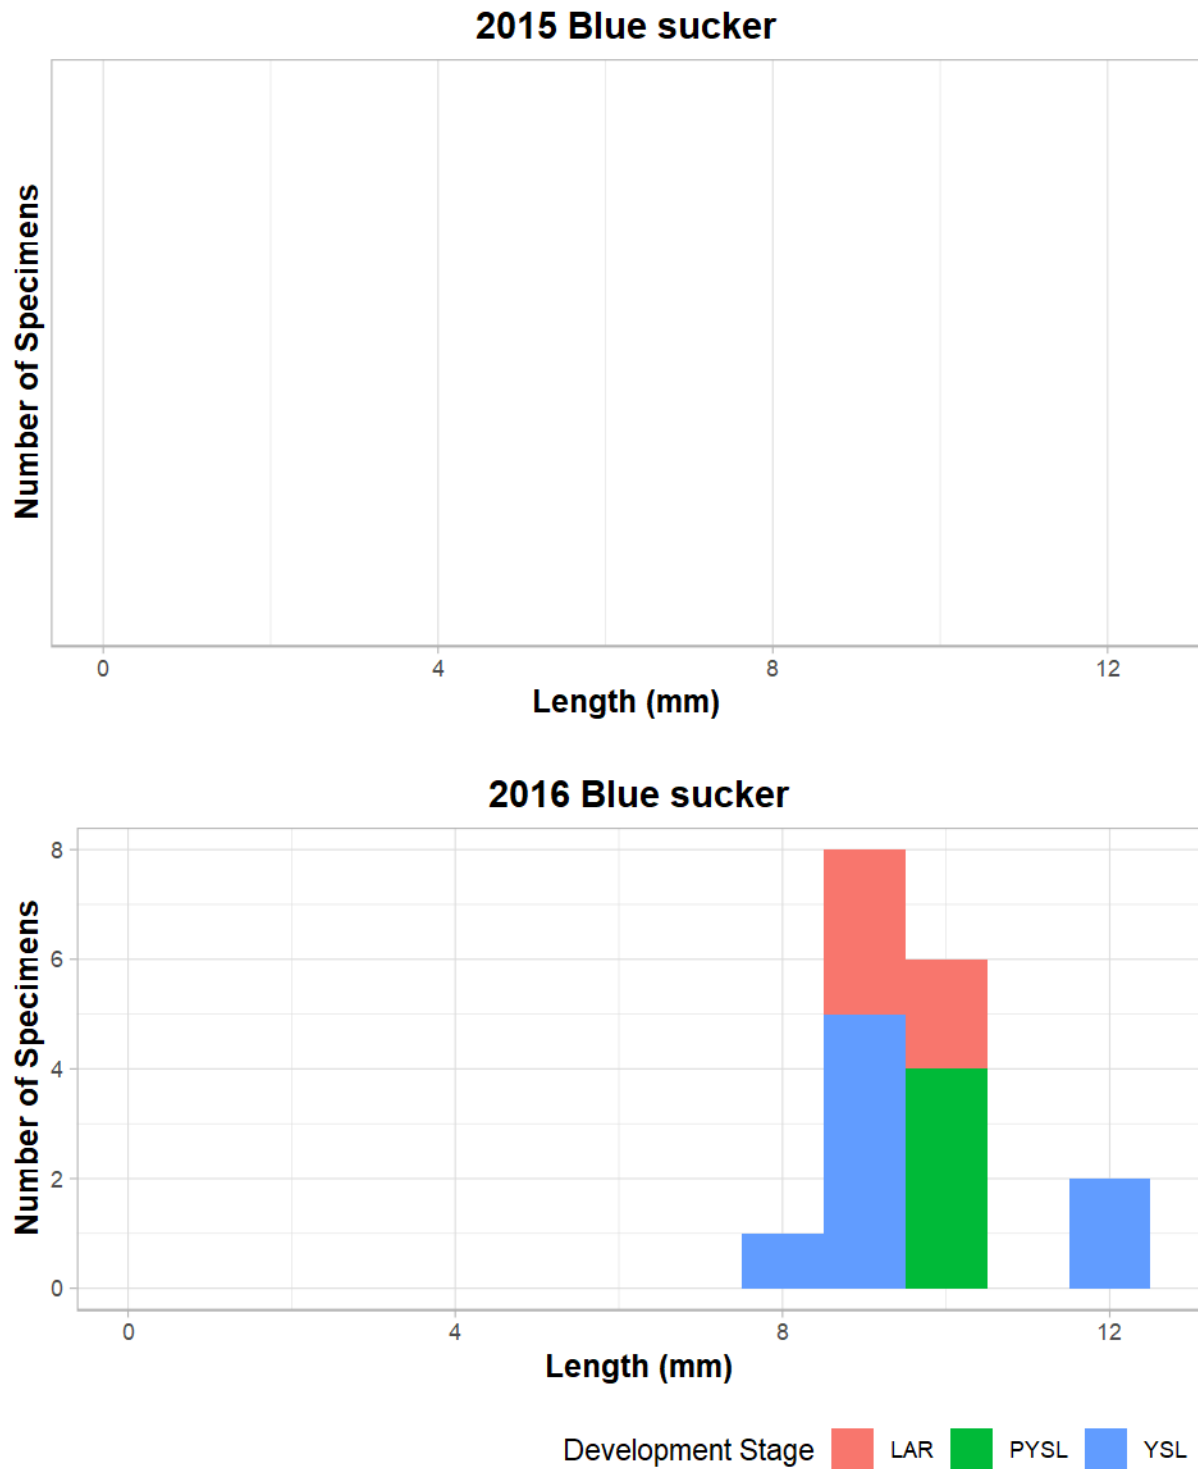

Figure 9 D-2 Length Histogram of Entrained Blue Sucker by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

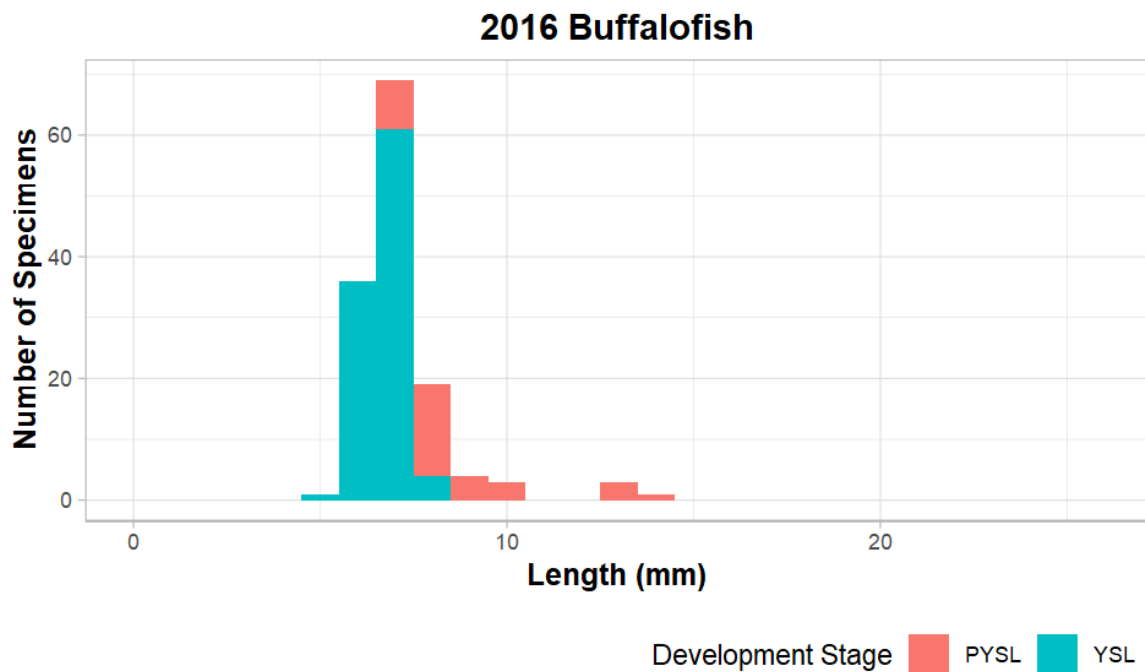

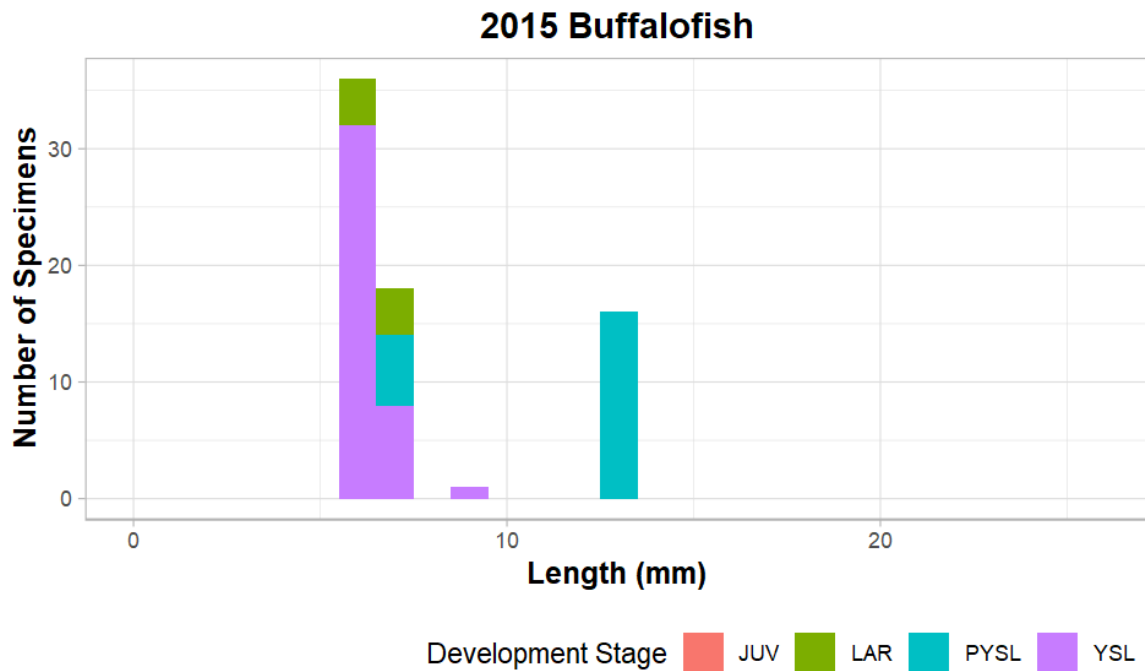

Figure 9 D-3 Length Histogram of Entrained Buffalos (*Ictiobus* sp.) by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

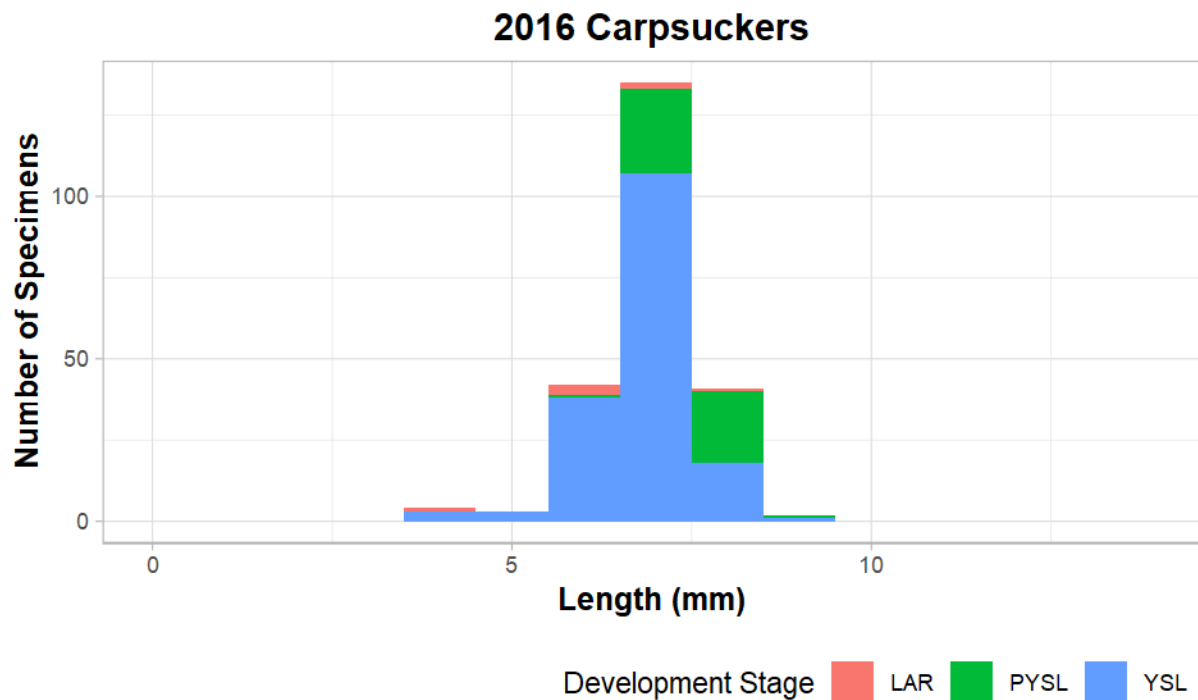

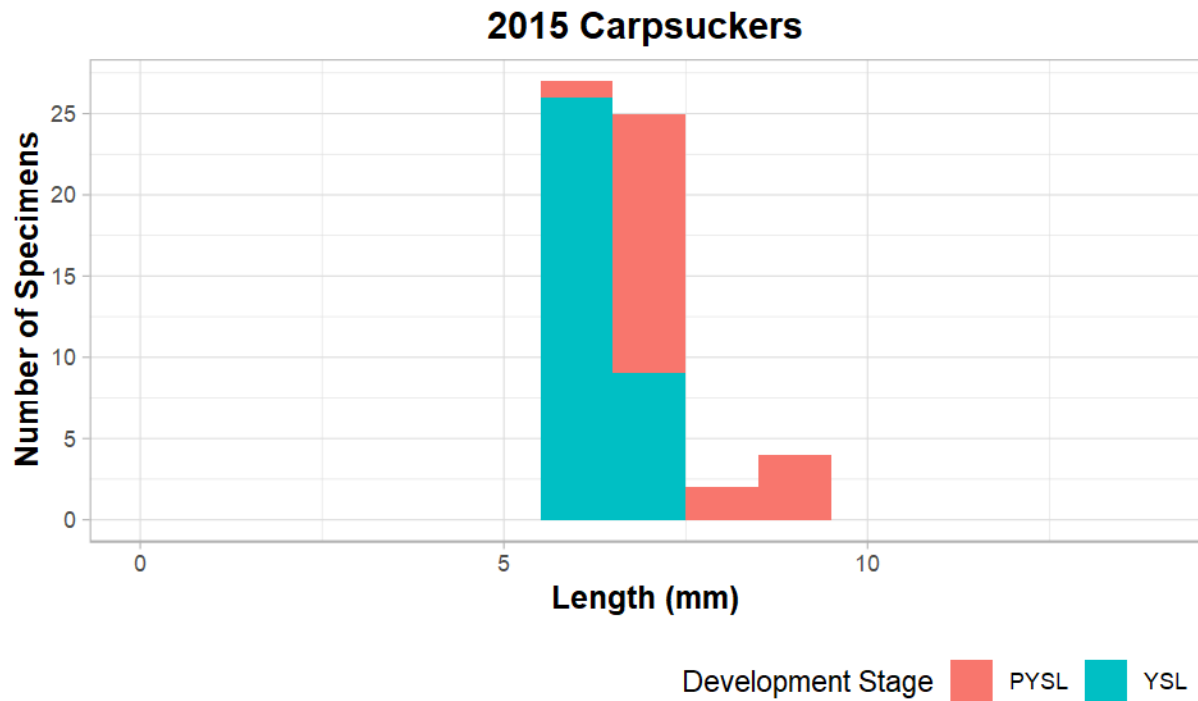

Figure 9 D-4 Length Histogram of Entrained Carpsuckers (*Carpionidae* sp.) by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

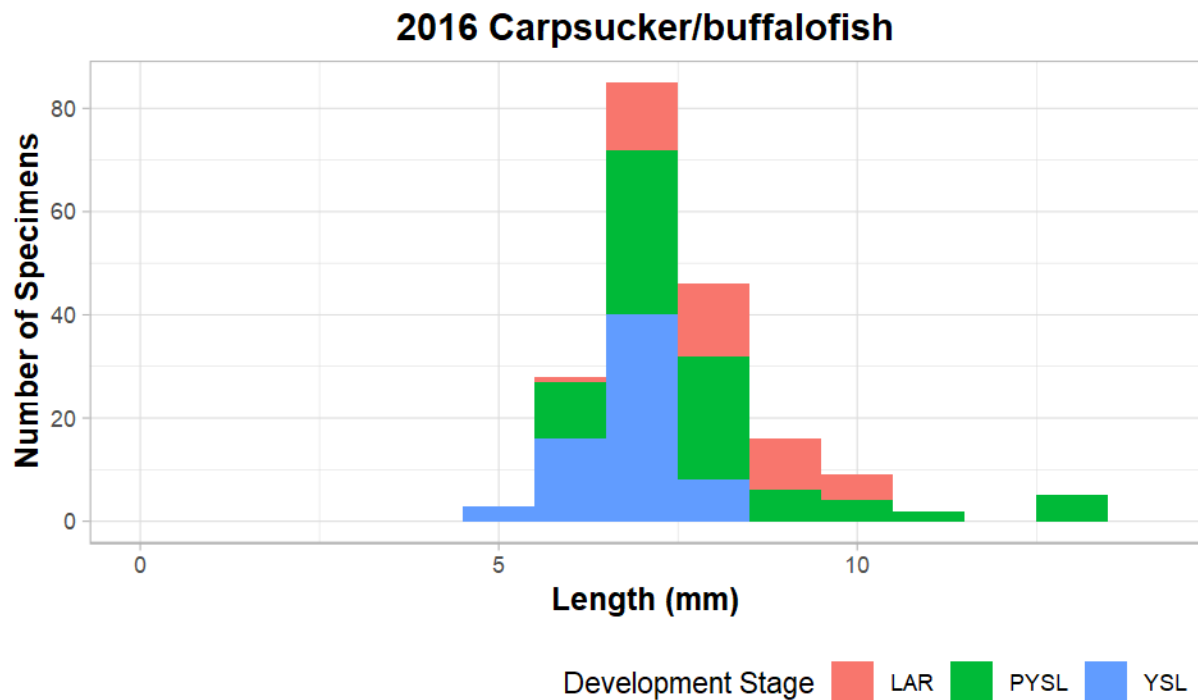

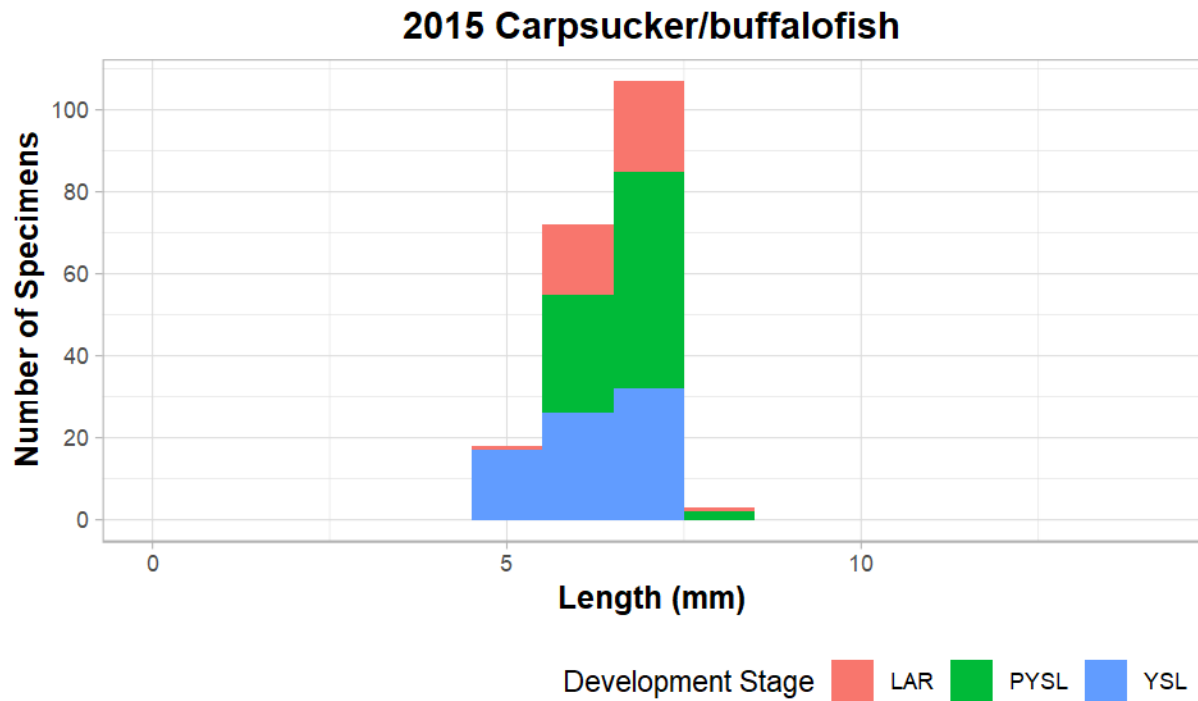

Figure 9 D-5 Length Histogram of Entrained Carpsuckers and Buffalos (Subfamily Ictiobinae) by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

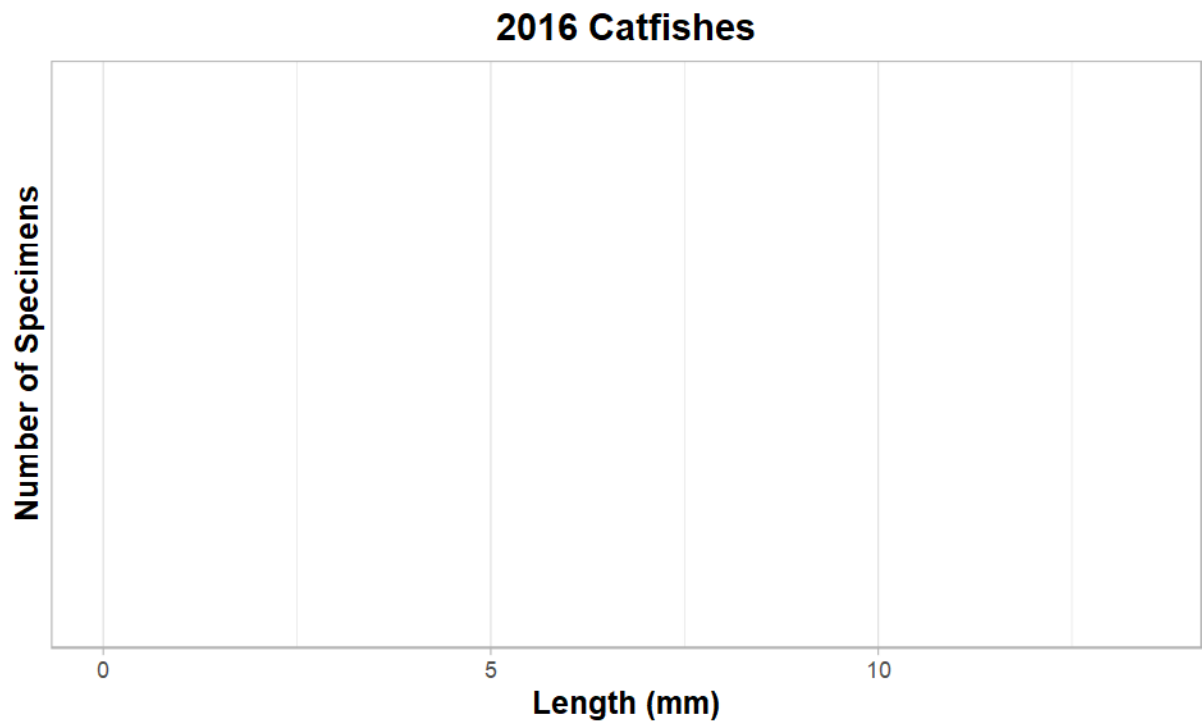

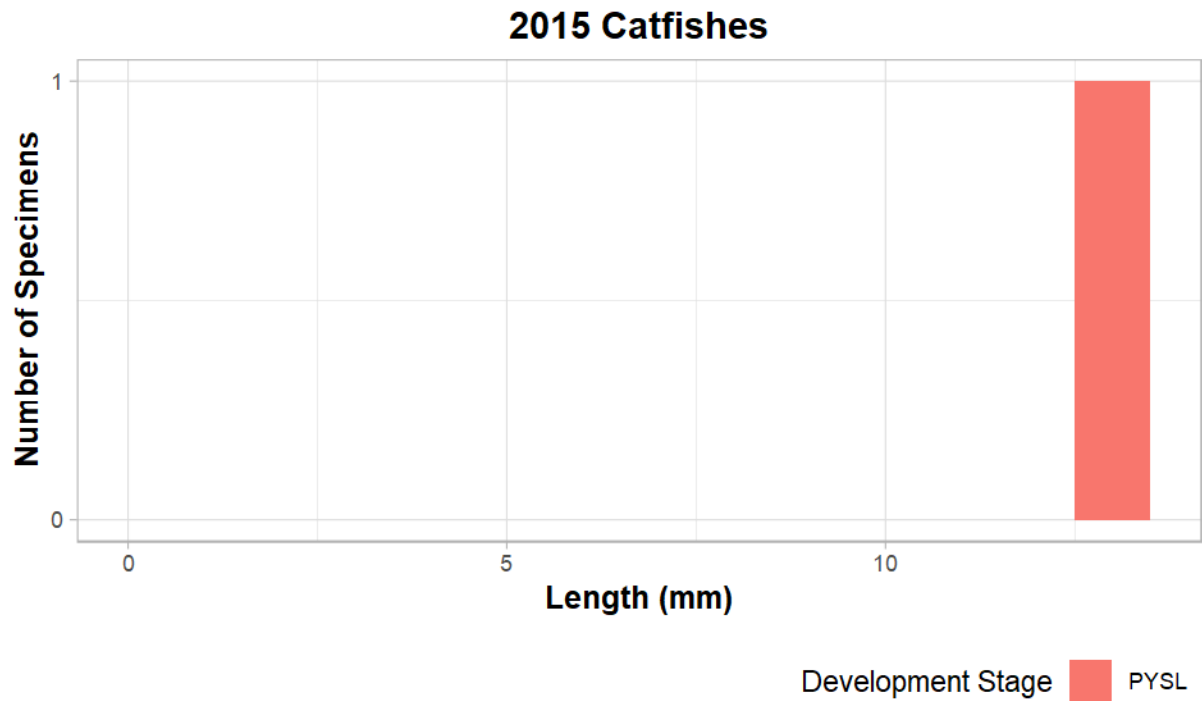

Figure 9 D-6 Length Histogram of Entrained North American Catfishes (Family Ictaluridae) by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

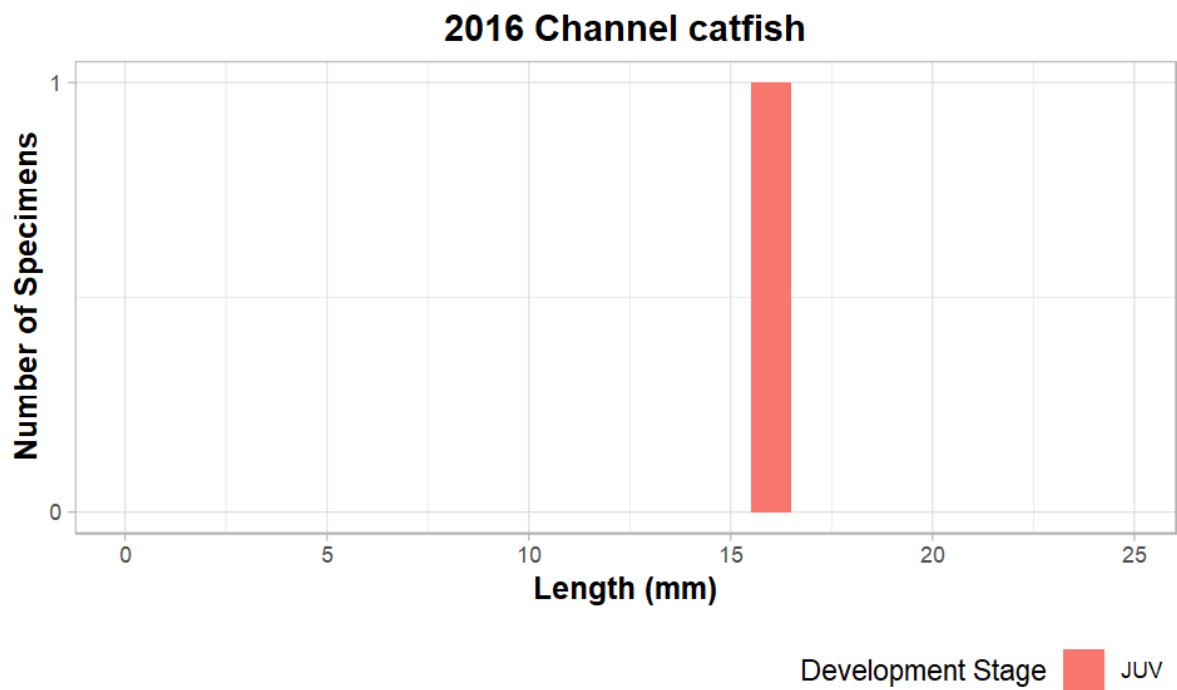

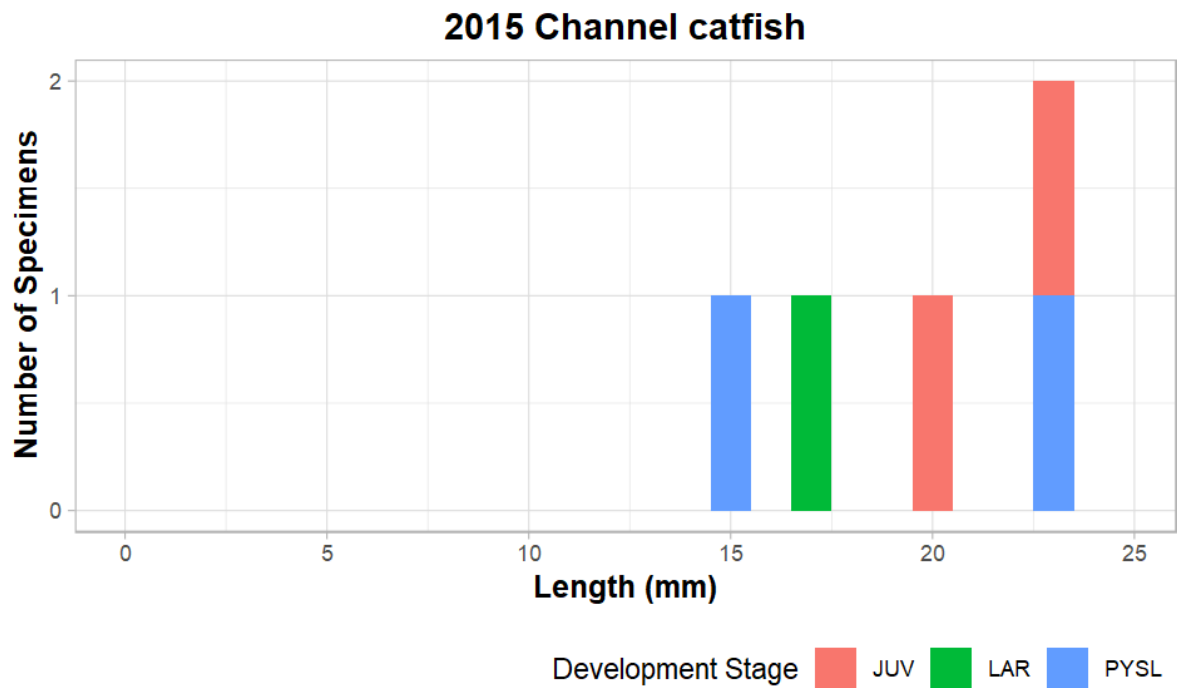

Figure 9 D-7 Length Histogram of Entrained Channel Catfish by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

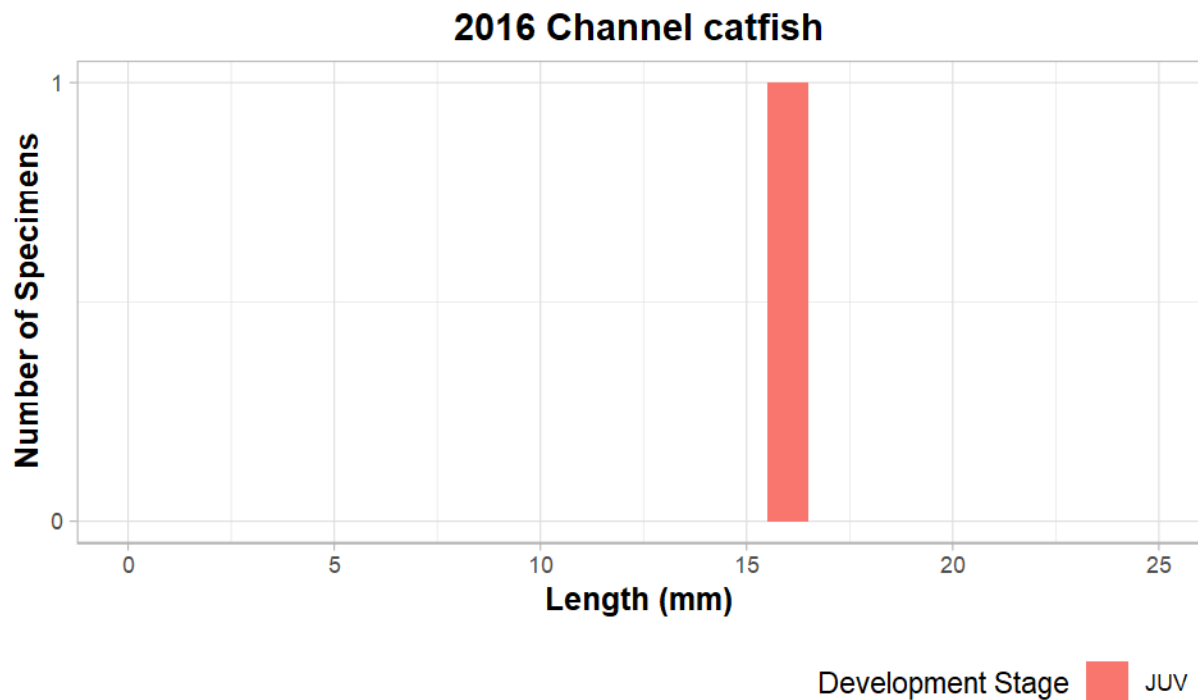

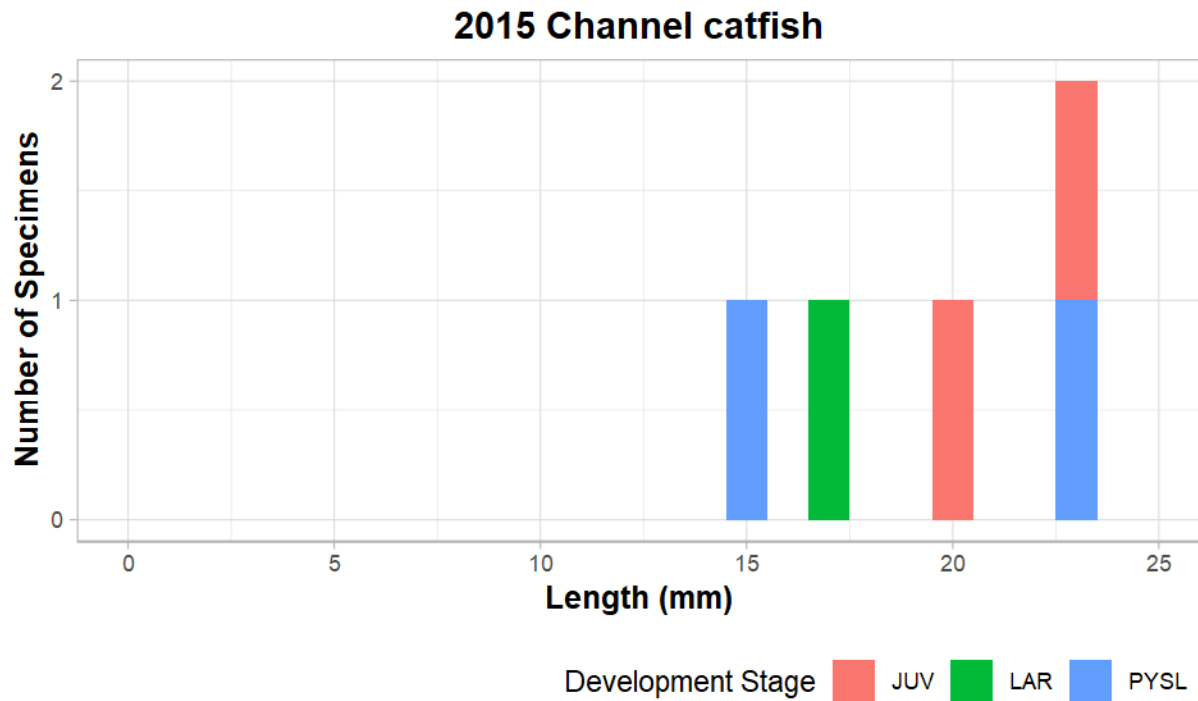

Figure 9 D-8 Length Histogram of Entrained Common Carp by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

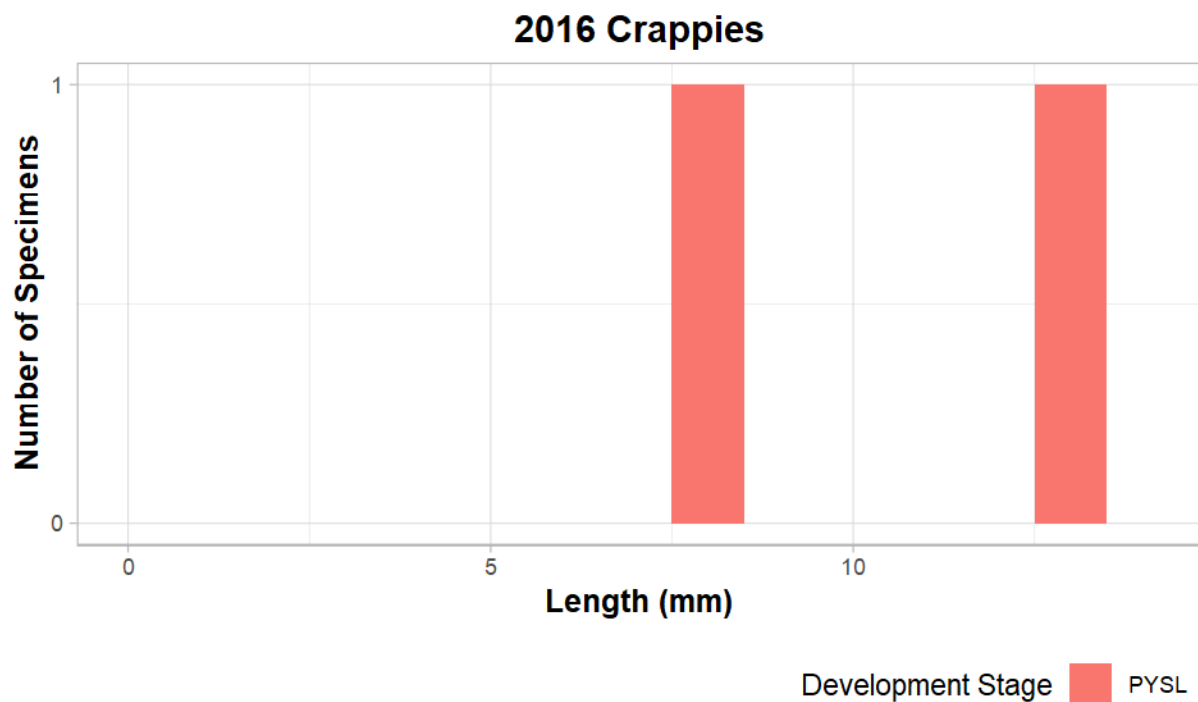

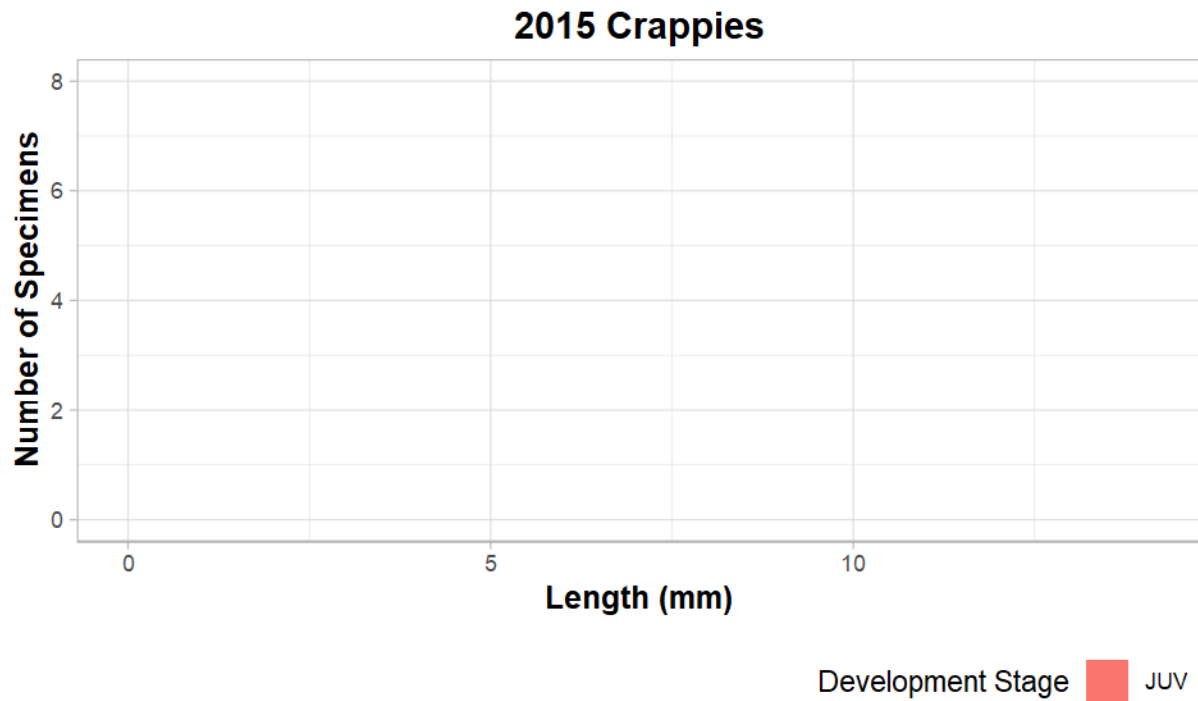

Figure 9 D-9 Length Histogram of Entrained Crappies (*Pomoxis* sp.) by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

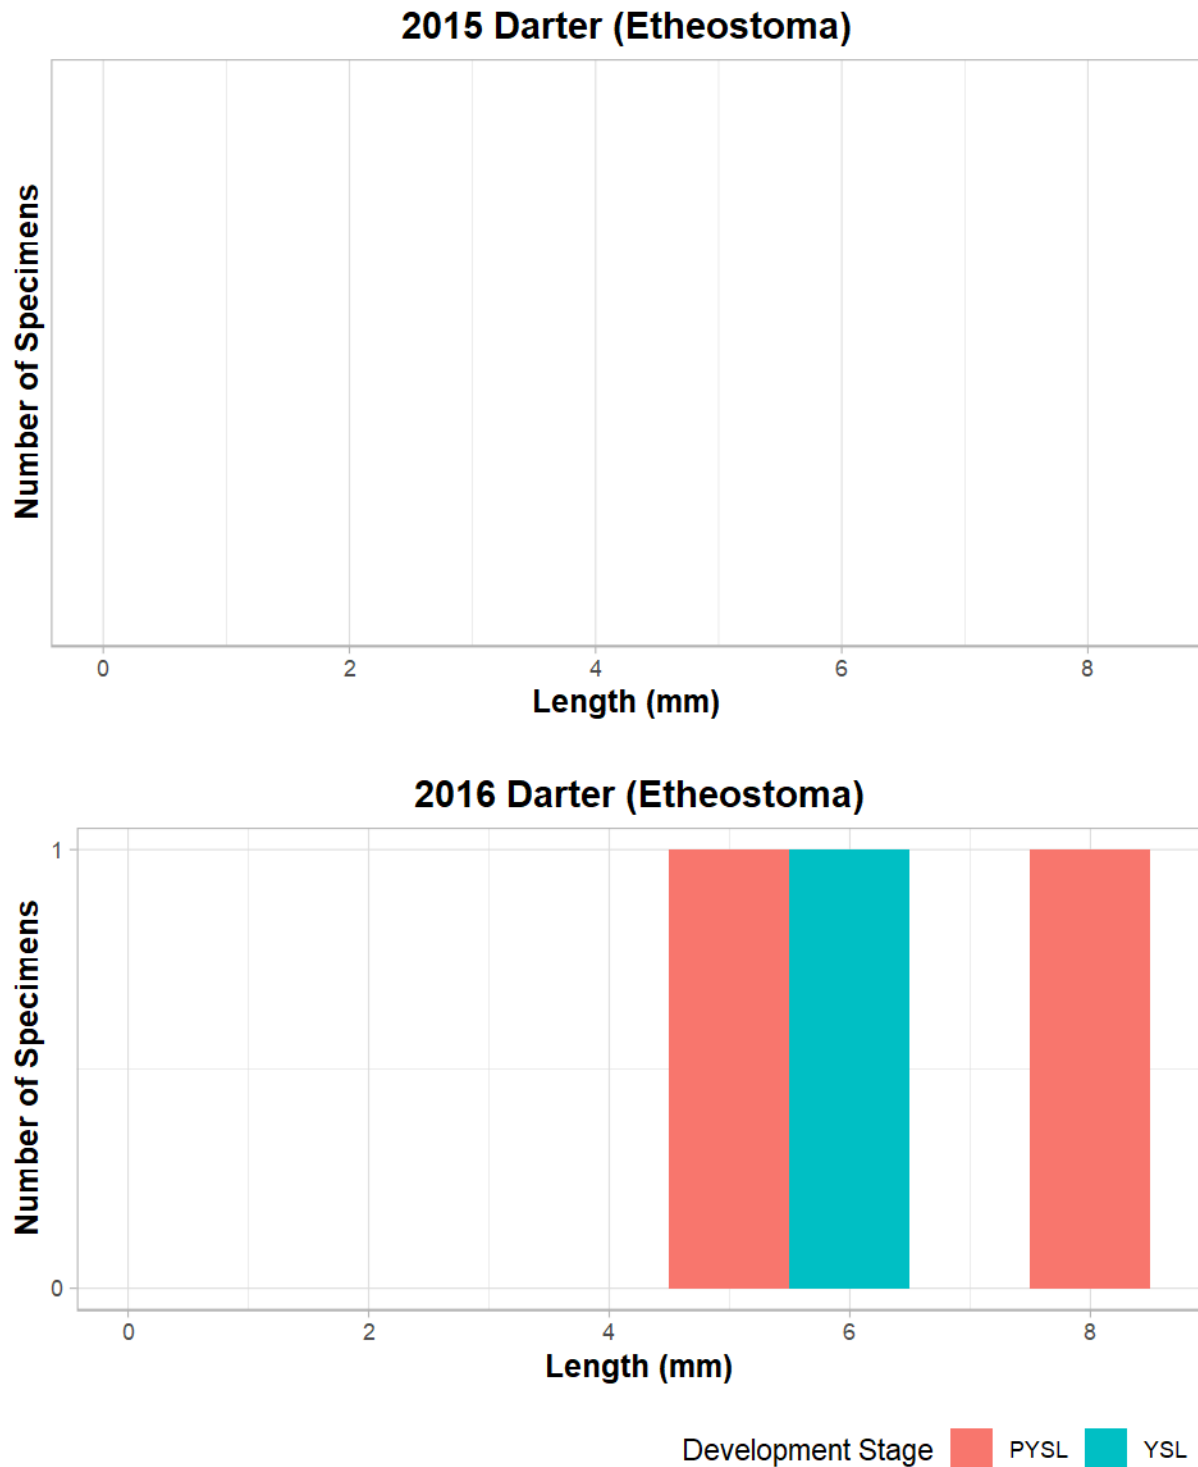

Figure 9 D-10 Length Histogram of Entrained Darters (*Etheostoma* sp.) by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

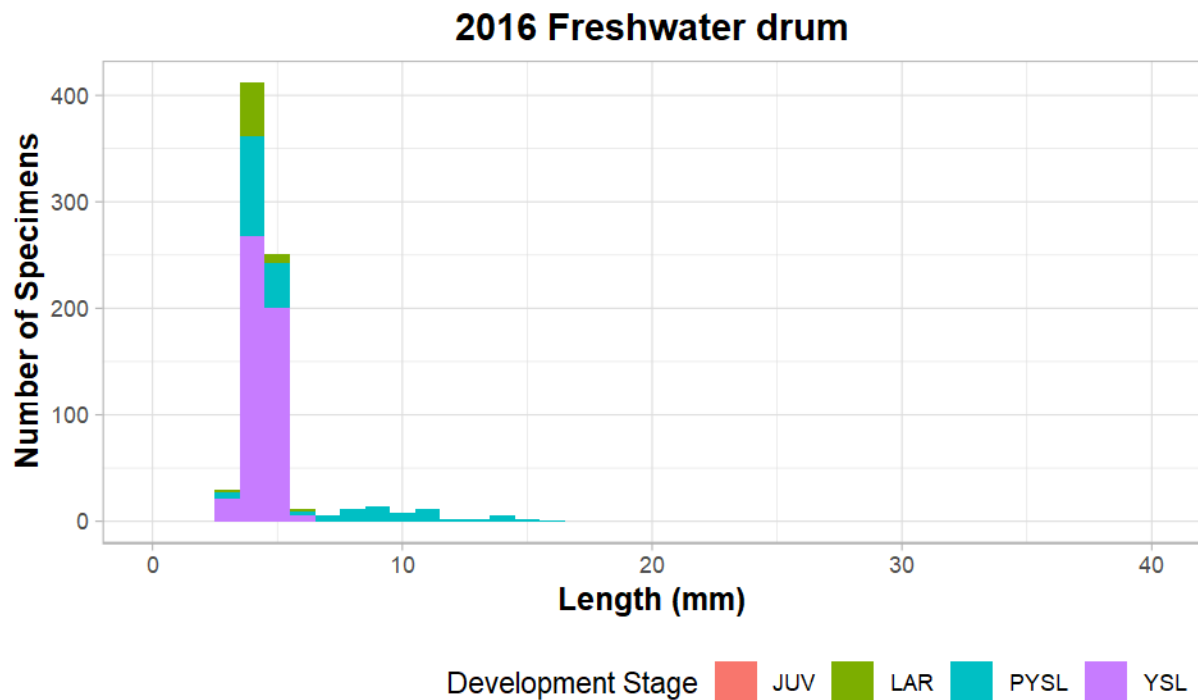

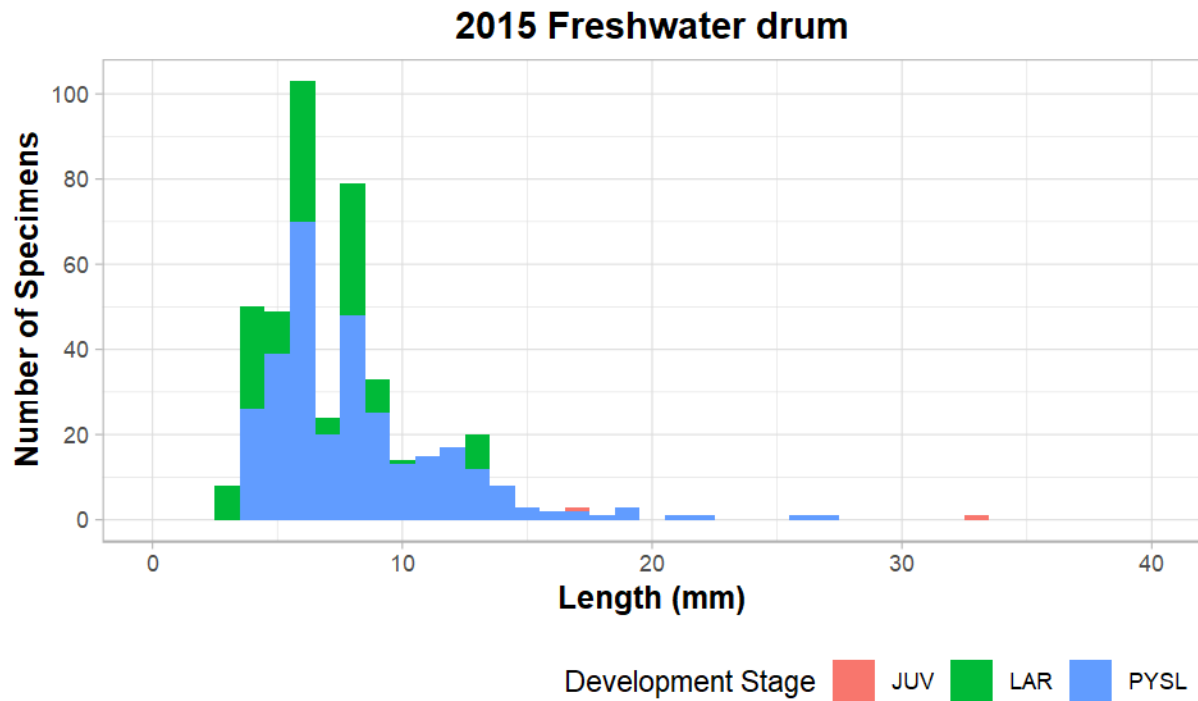

Figure 9 D-11 Length Histogram of Entrained Freshwater Drum by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

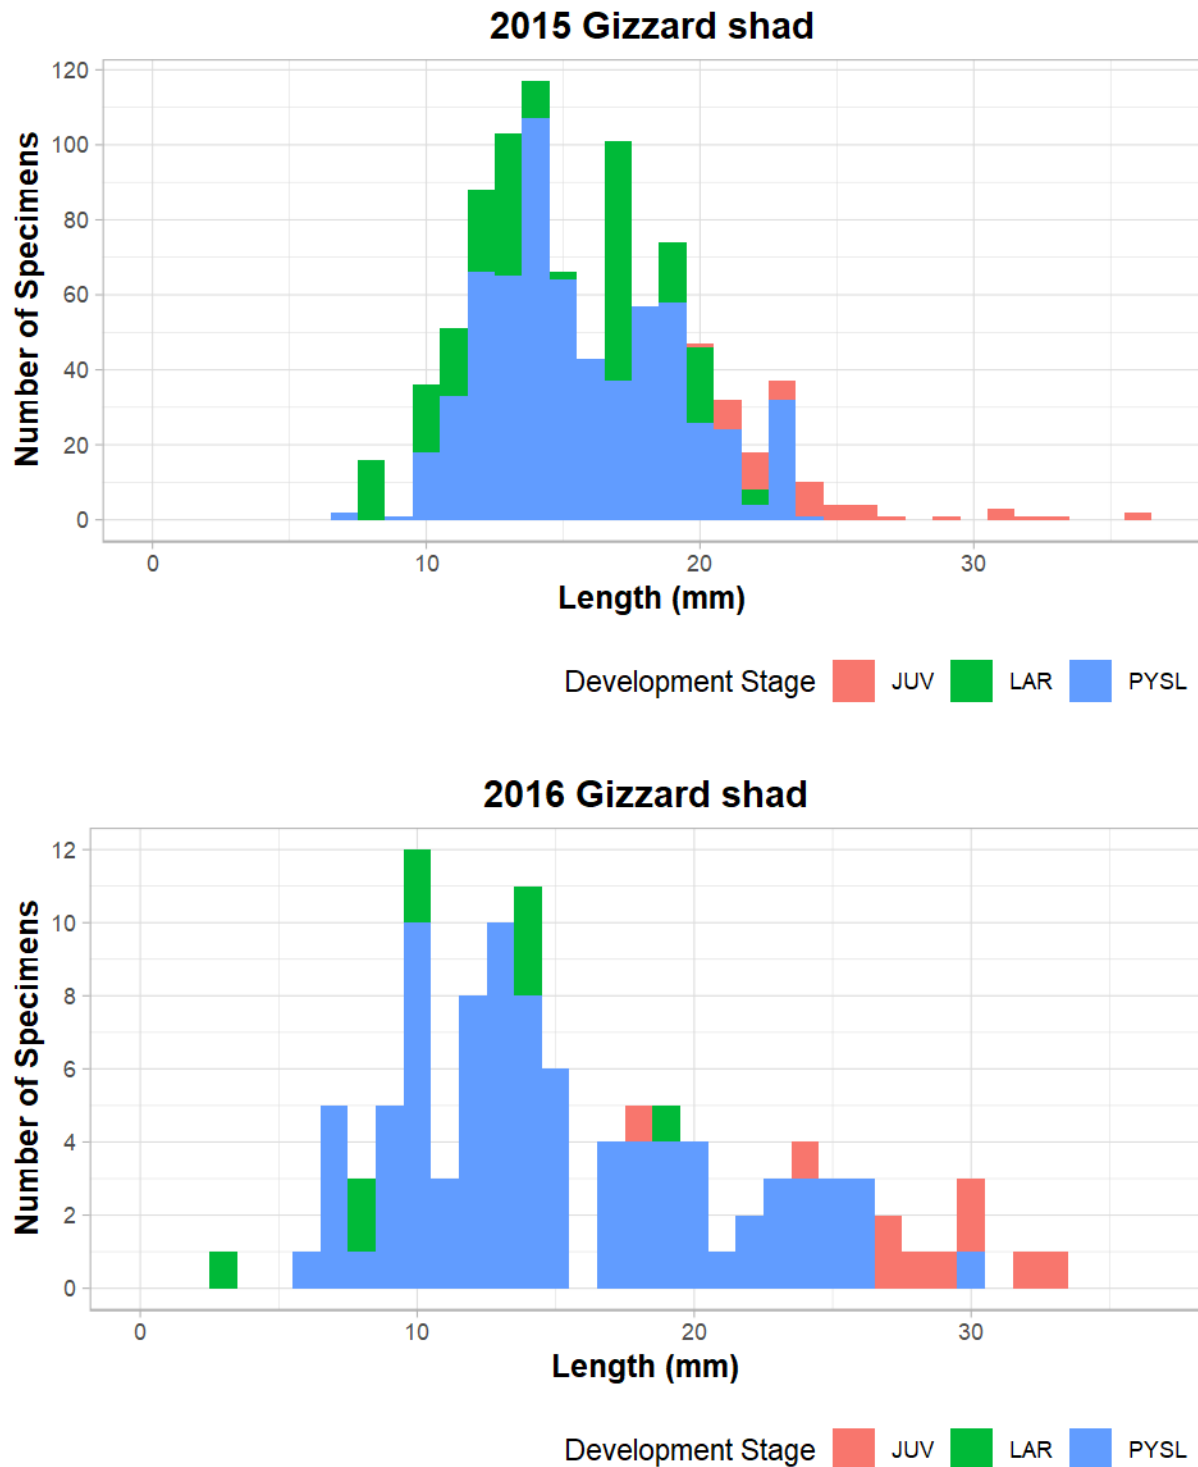

Figure 9 D-12 Length Histogram of Entrained Gizzard Shad by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

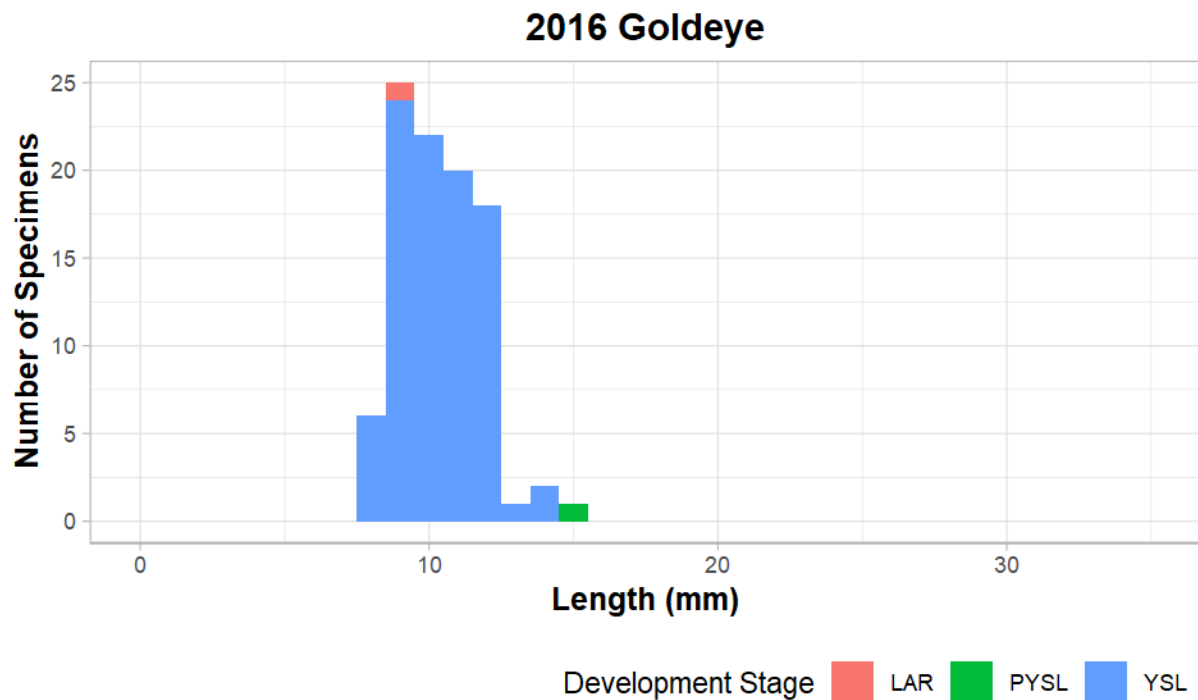

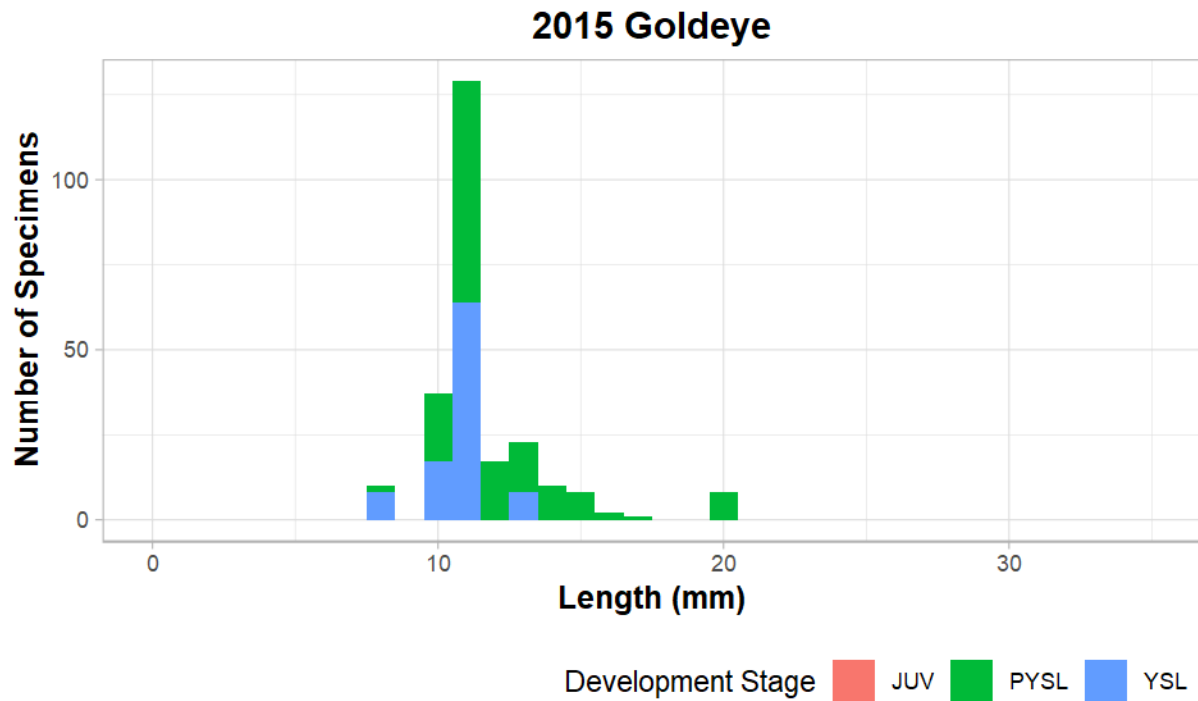

Figure 9 D-13 Length Histogram of Entrained Goldeye by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

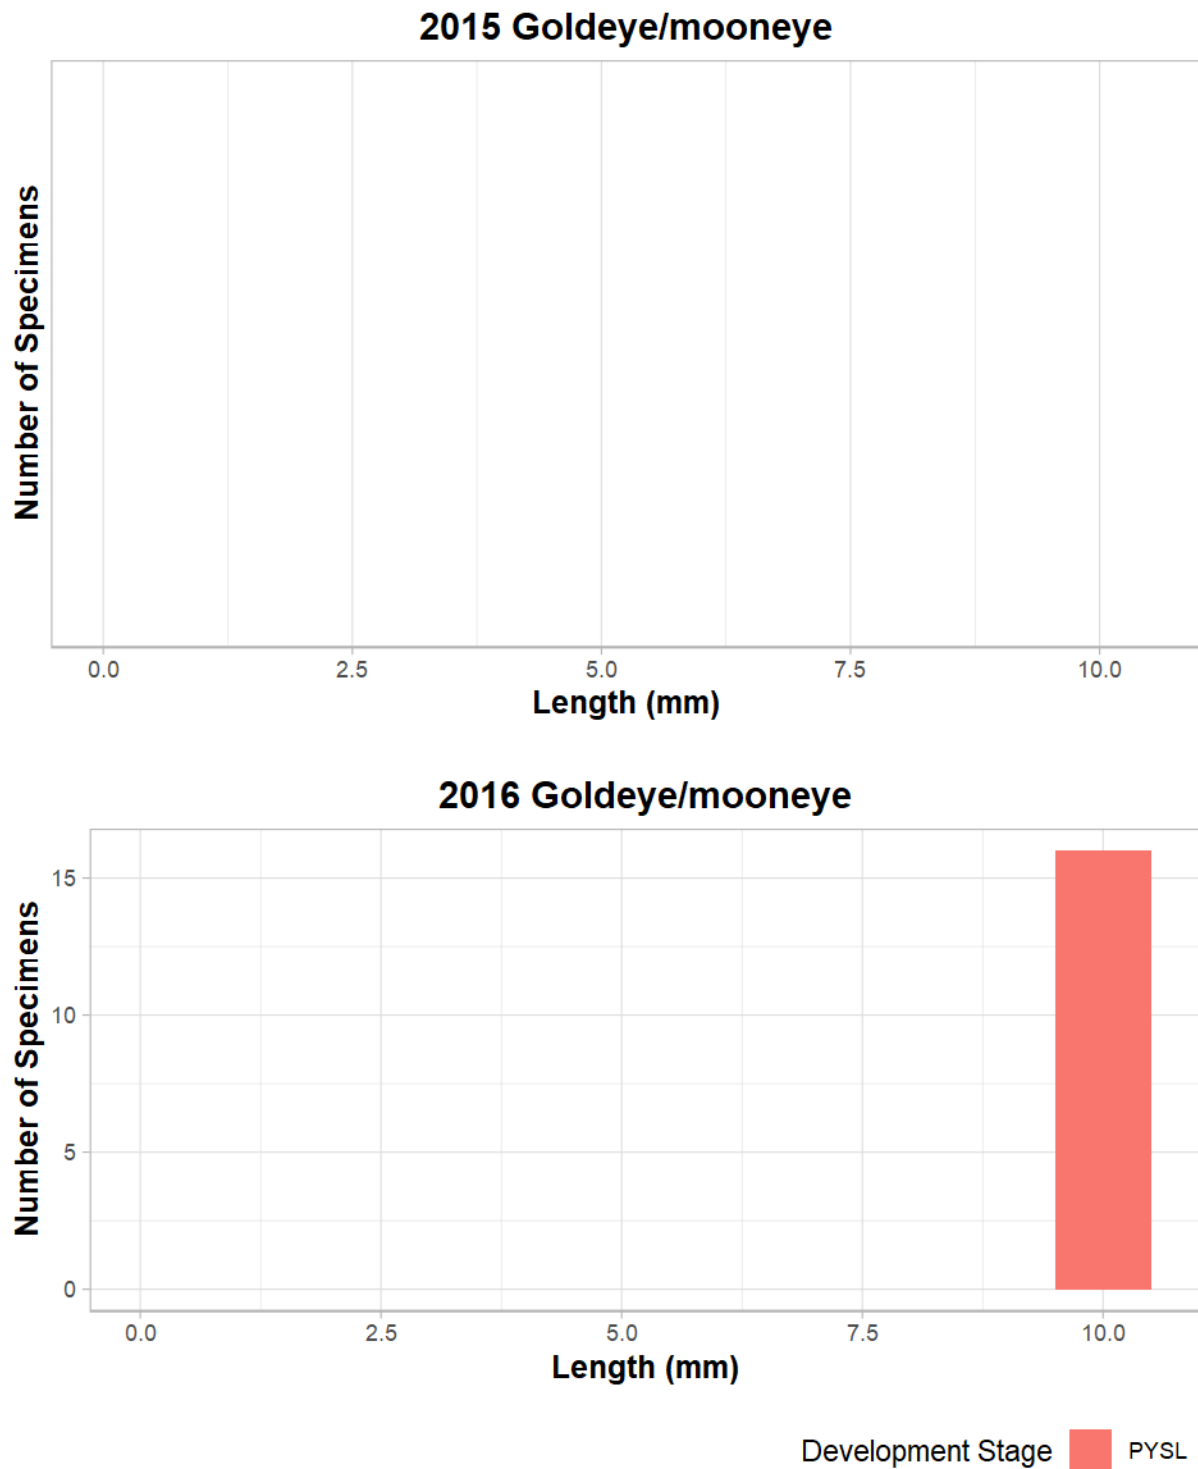

Figure 9 D-14 Length Histogram of Entrained Mooneyes (*Hiodon* sp.) by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

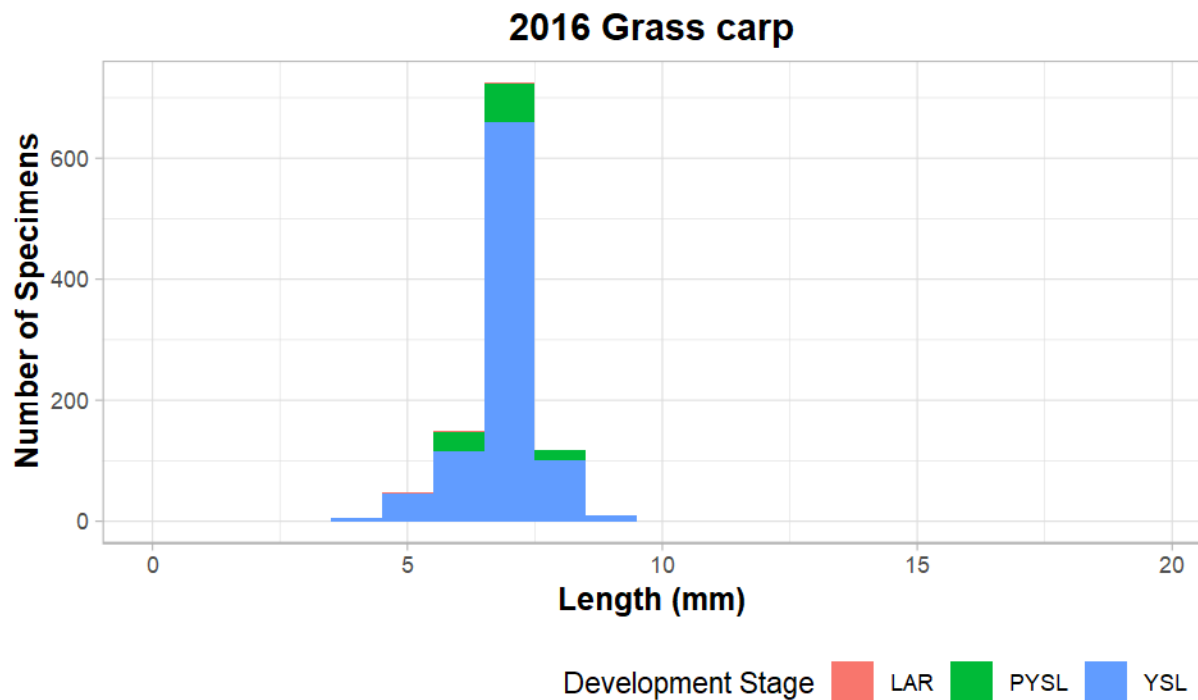

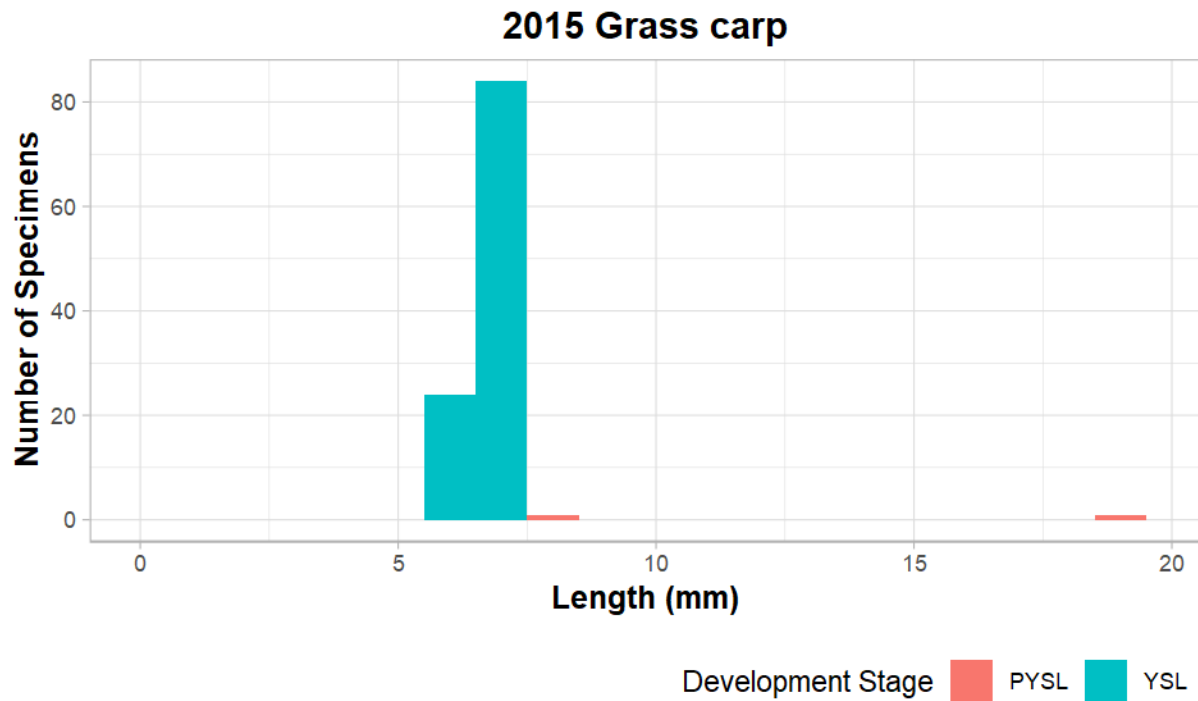

Figure 9 D-15 Length Histogram of Entrained Grass Carp by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

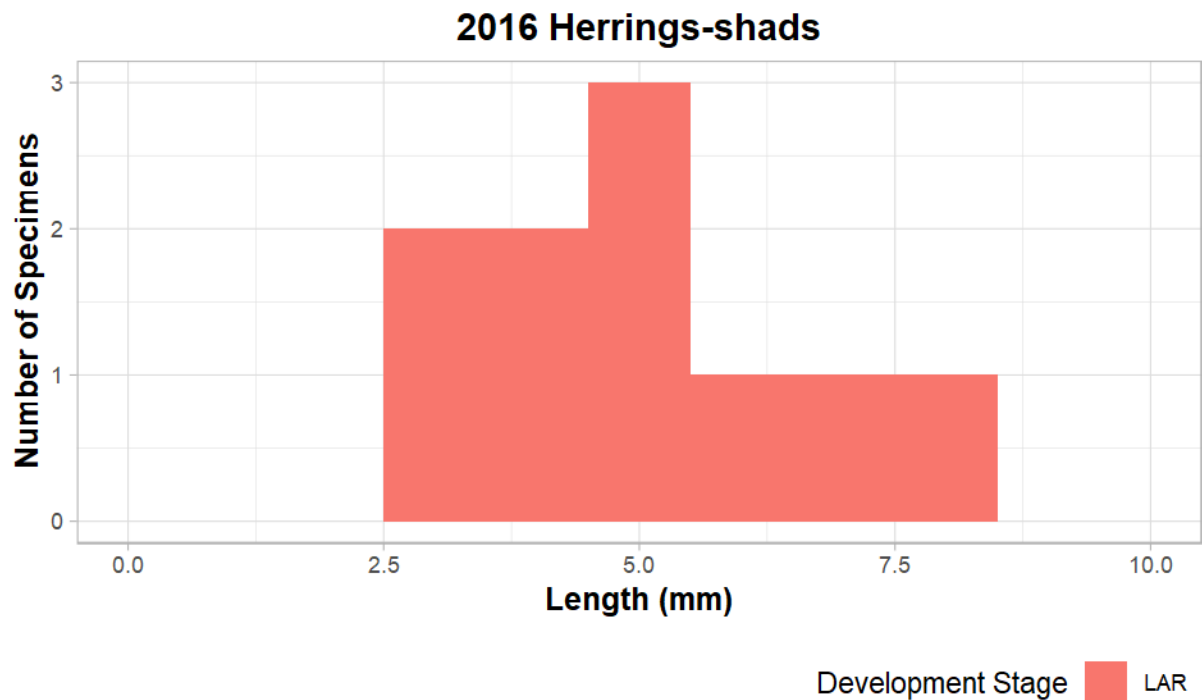

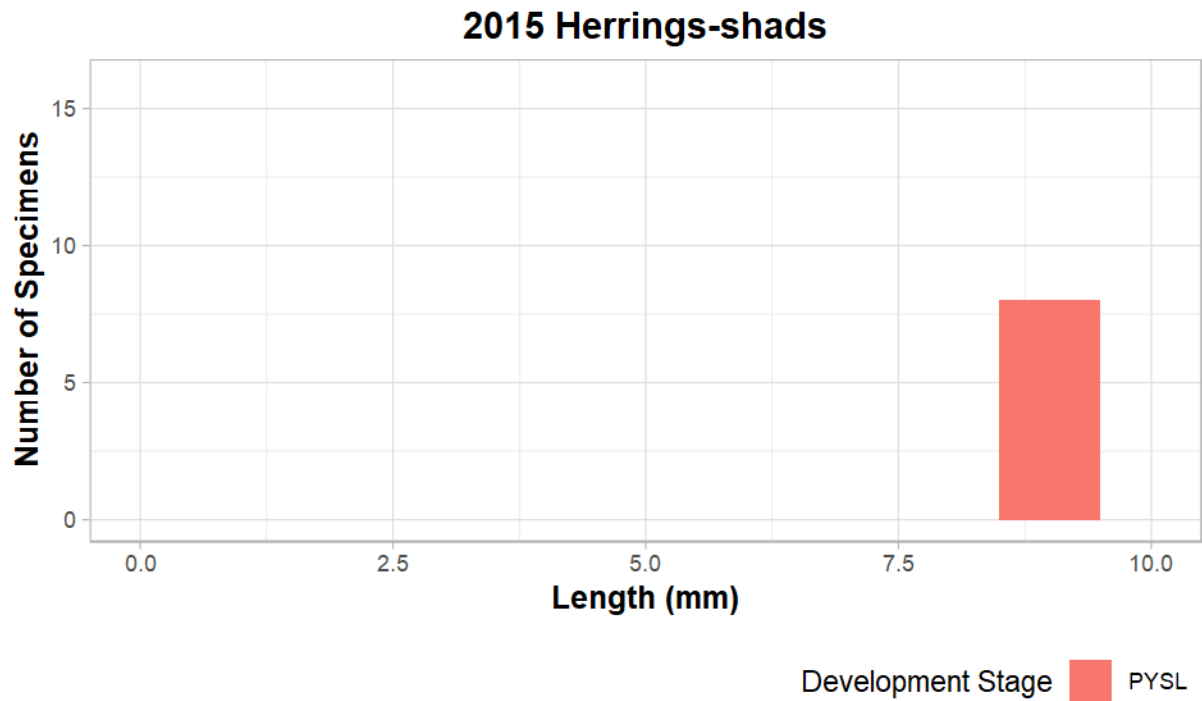

Figure 9 D-16 Length Histogram of Entrained Shads (*Dorosoma* sp.) by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

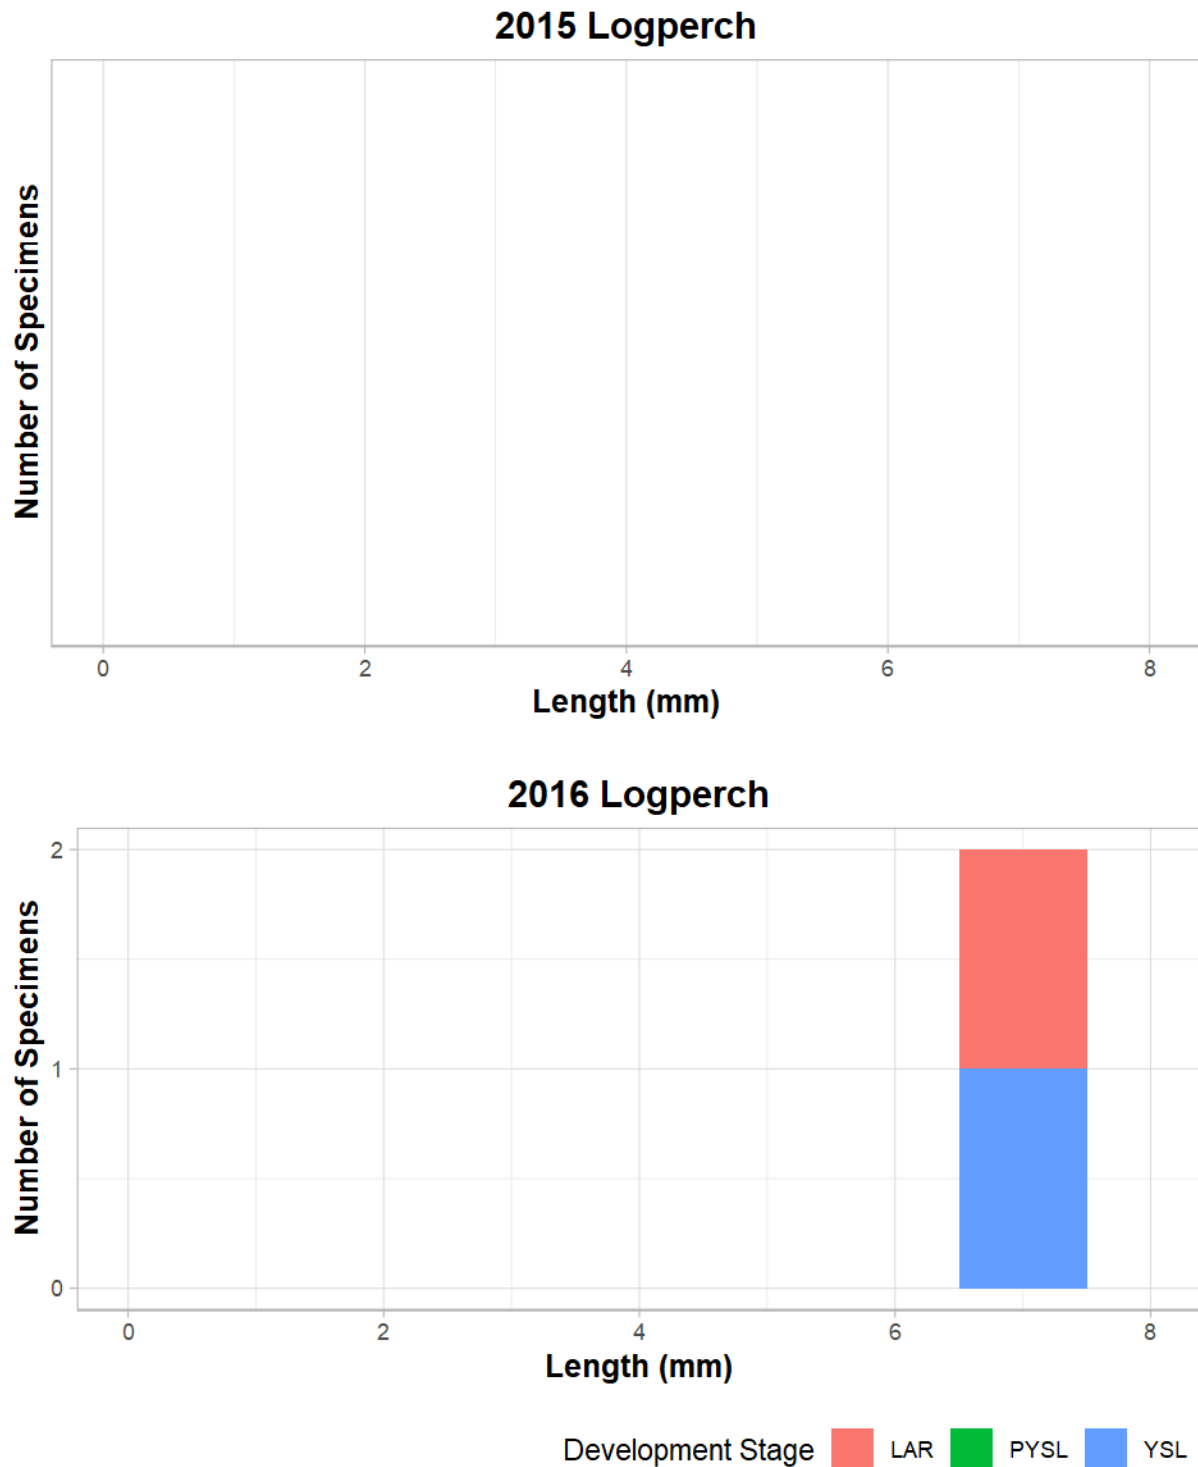

Figure 9 D-17 Length Histogram of Entrained Logperch by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

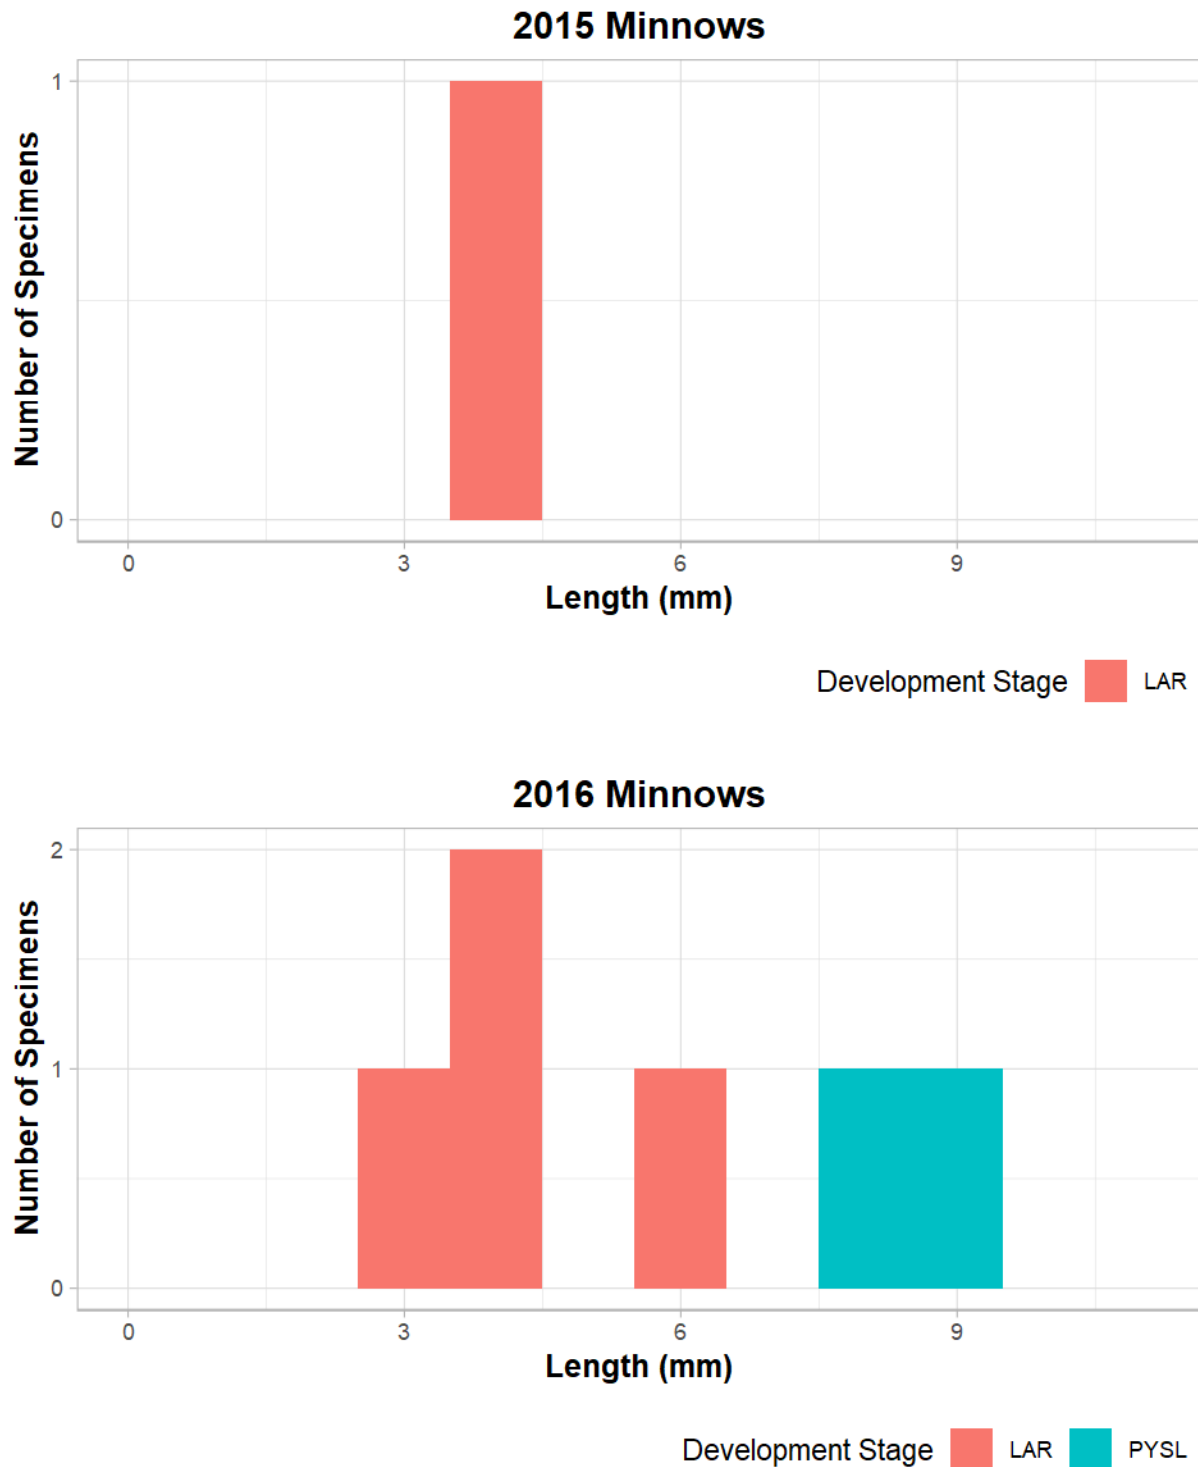

Figure 9 D-18 Length Histogram of Entrained Minnow Family (Cyprinidae) Fishes by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

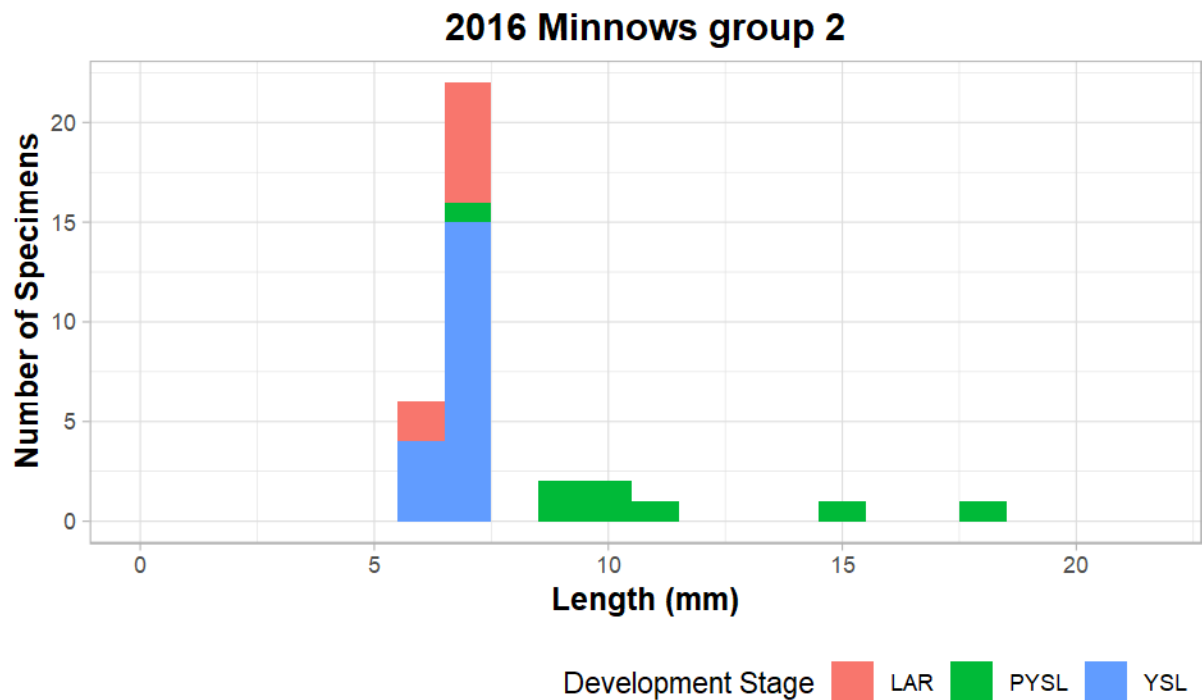

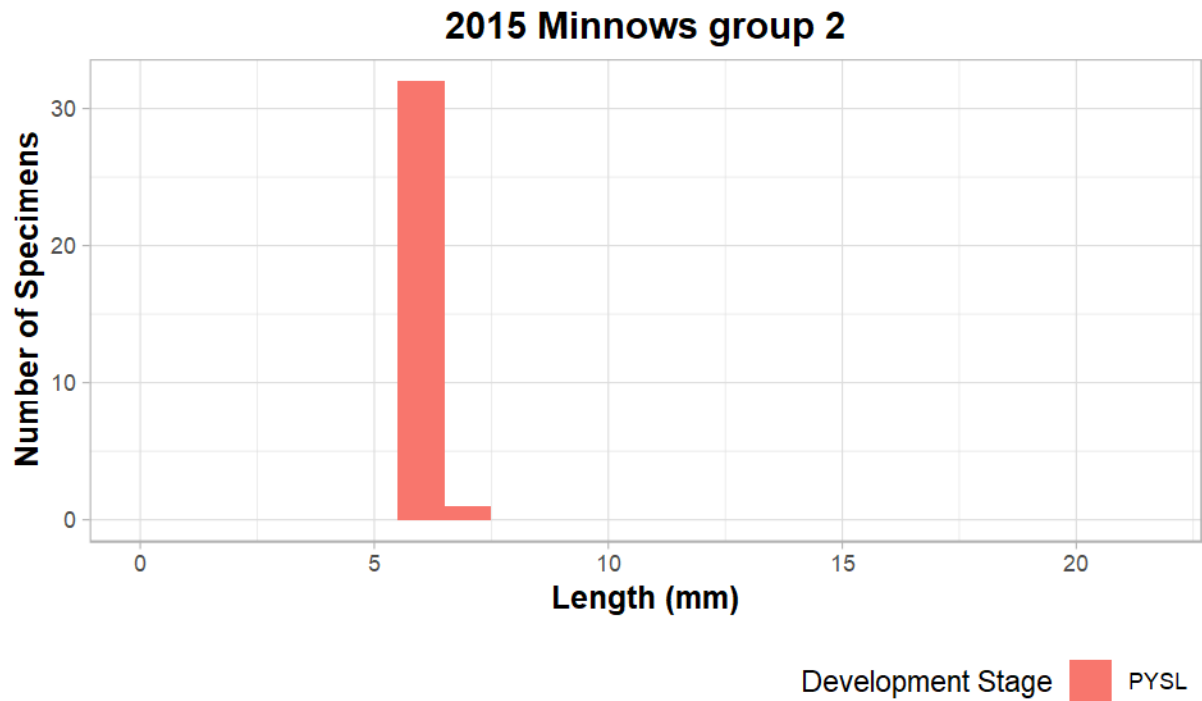

Figure 9 D-19 Length Histogram of Entrained Minnow Group 2 Fishes by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

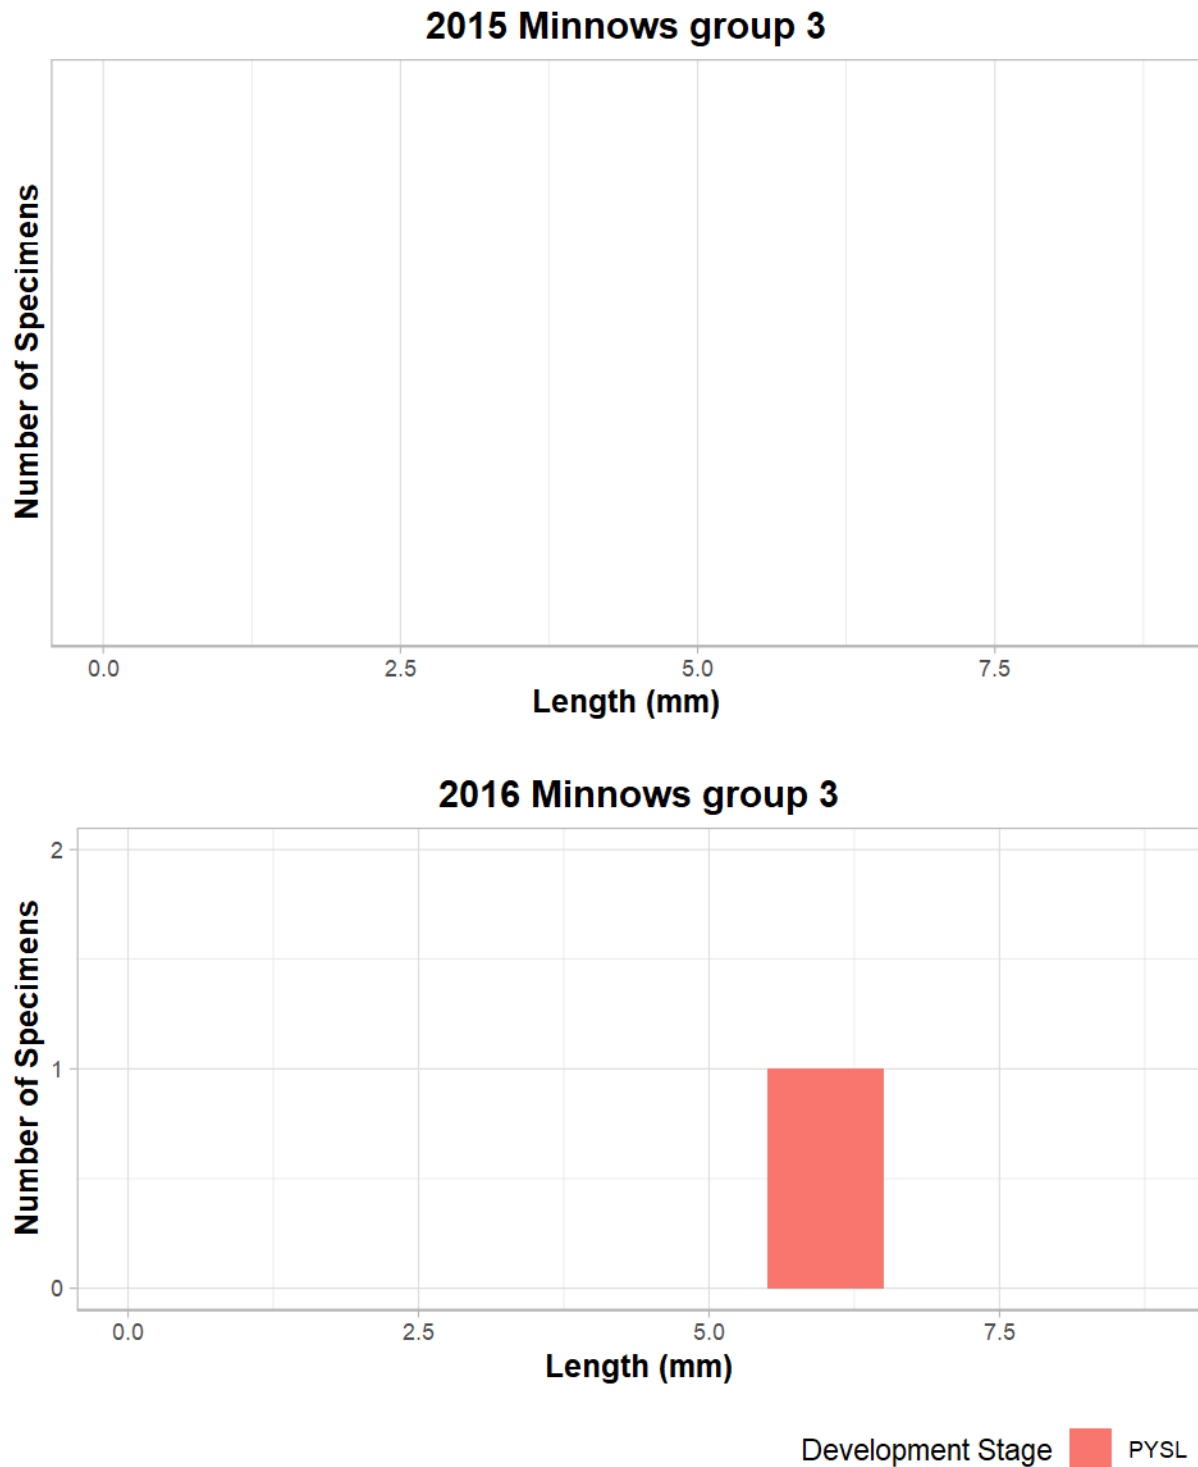

Figure 9 D-20 Length Histogram of Entrained Minnow Group 3 Fishes by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

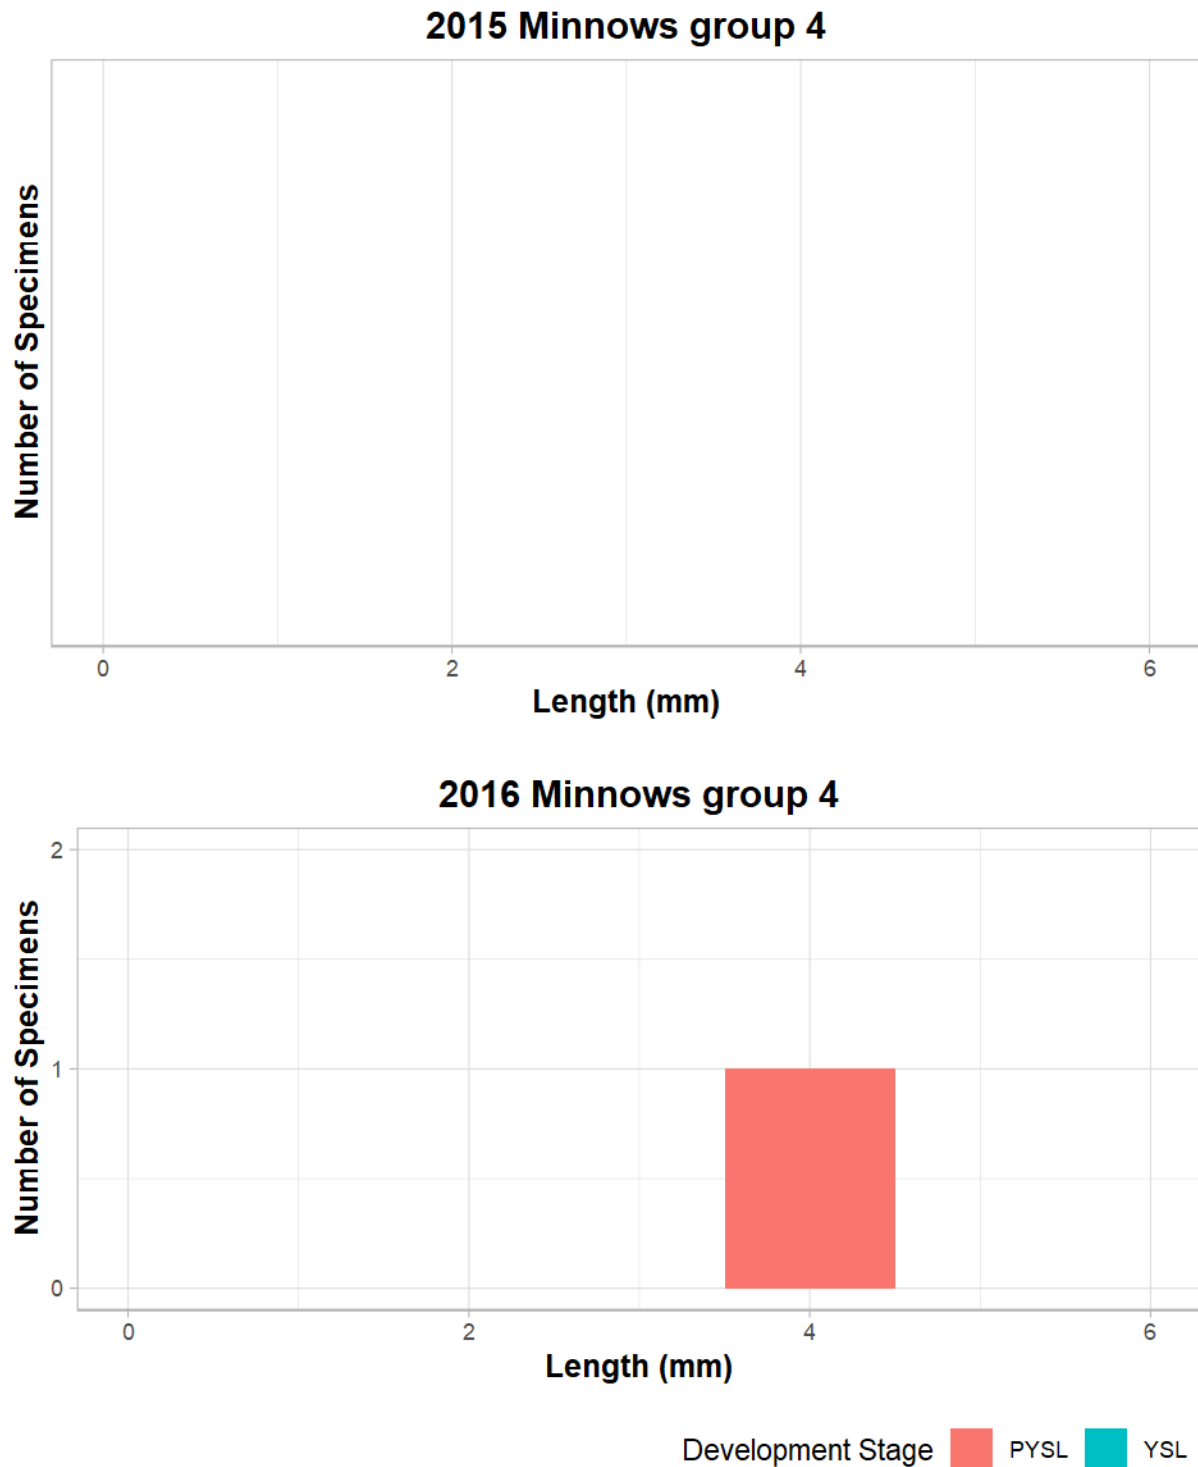

Figure 9 D-21 Length Histogram of Entrained Minnow Group 4 Fishes by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

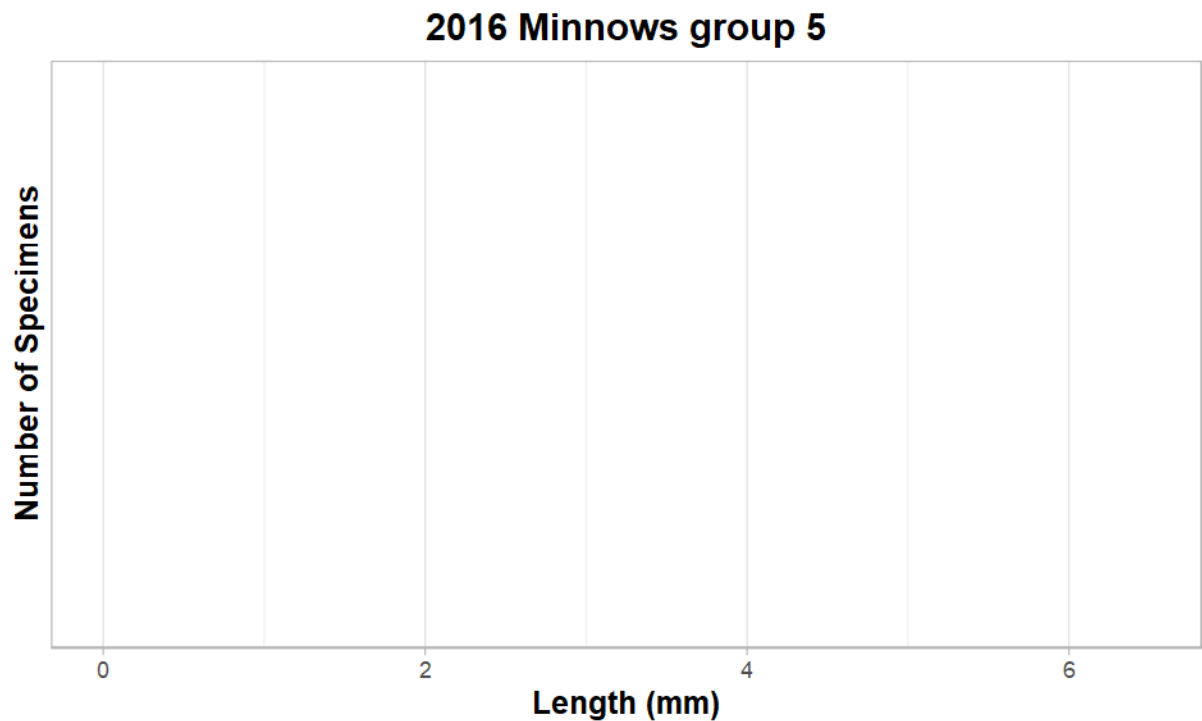

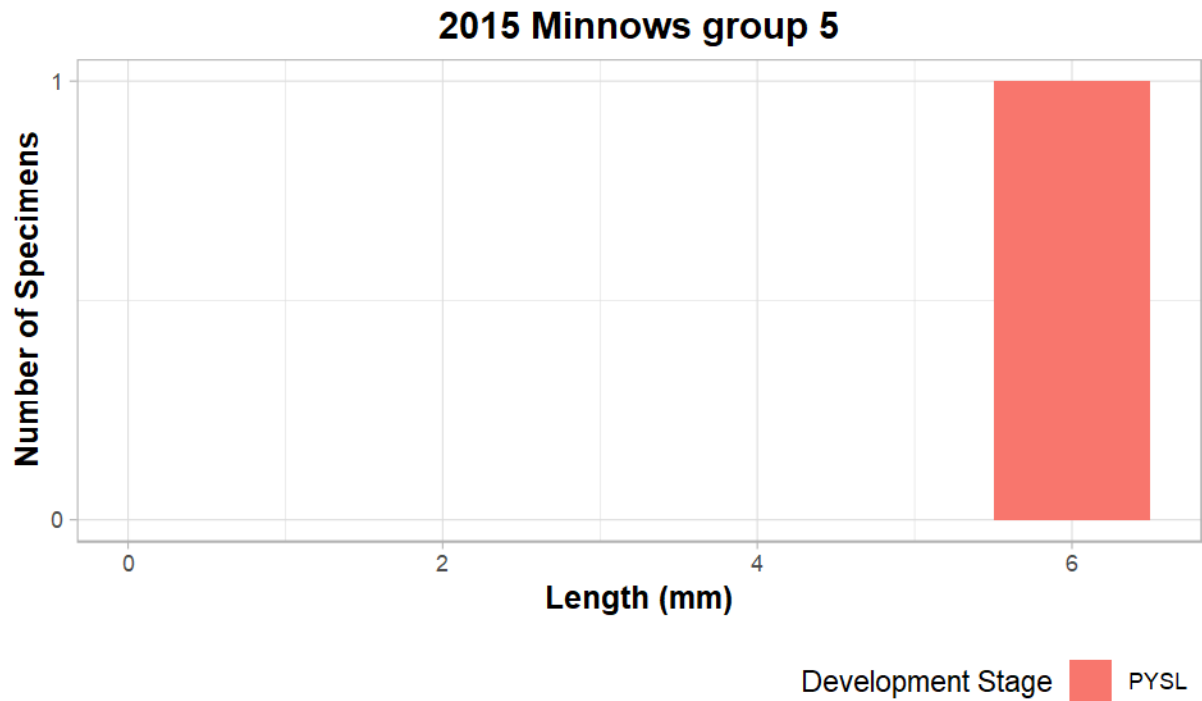

Figure 9 D-22 Length Histogram of Entrained Minnow Group 5 Fishes by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

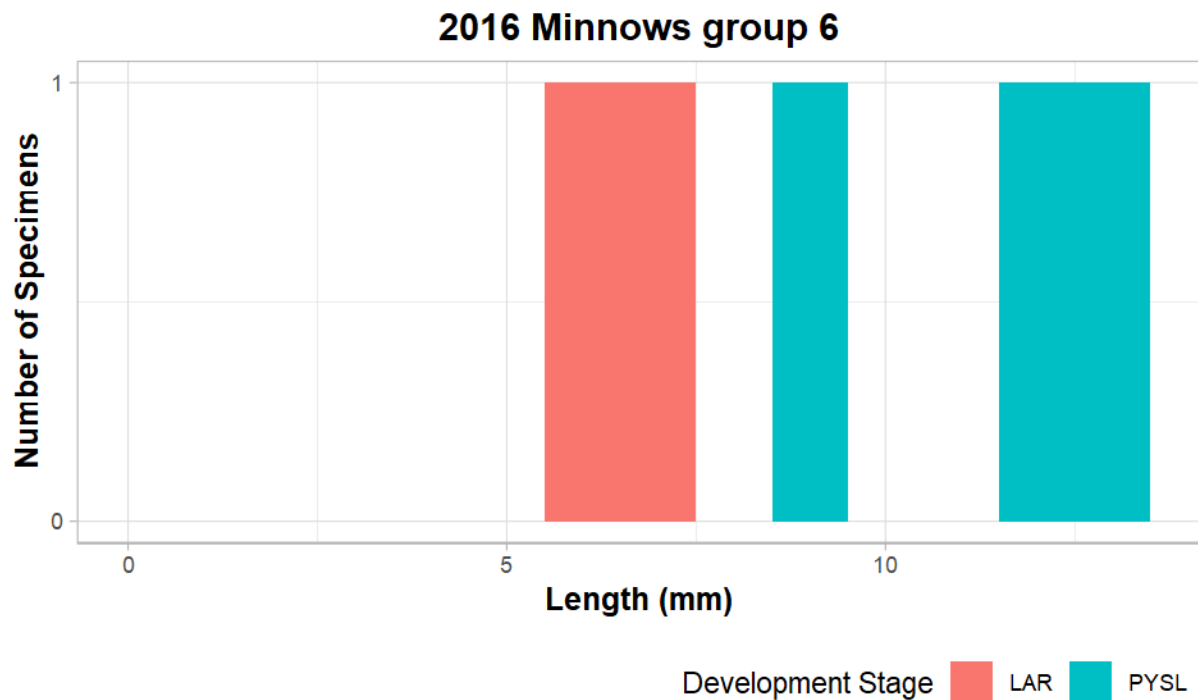

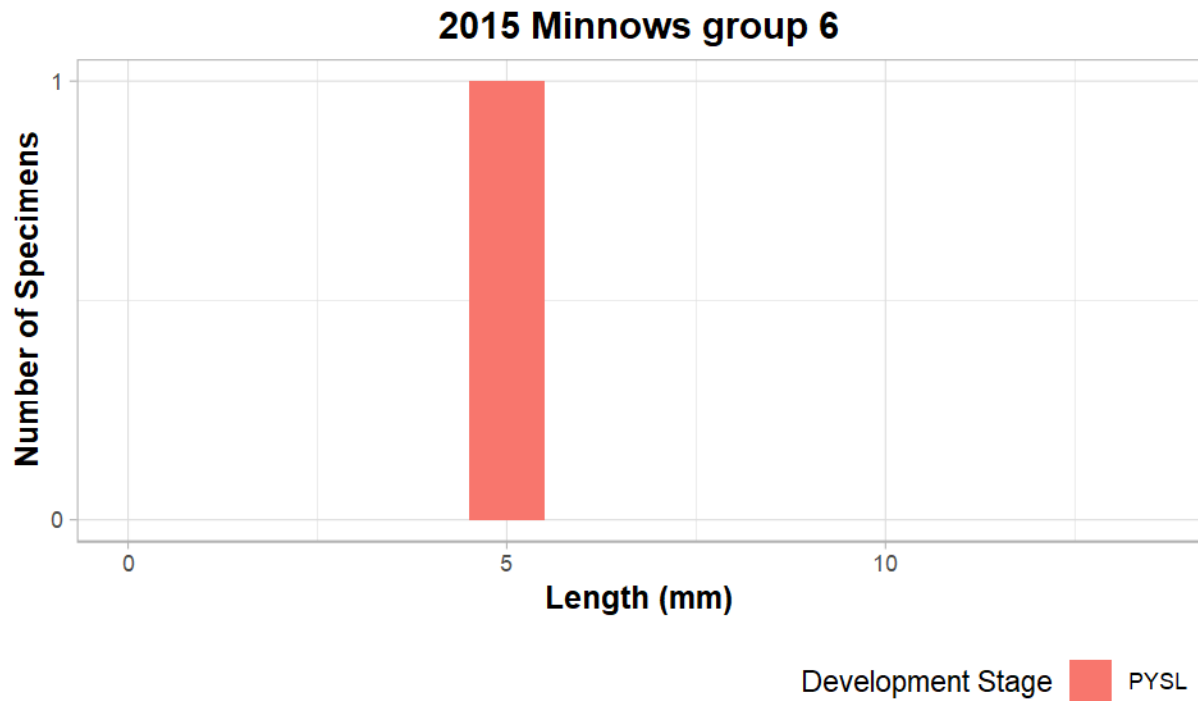

Figure 9 D-23 Length Histogram of Entrained Minnow Group 6 Fishes by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

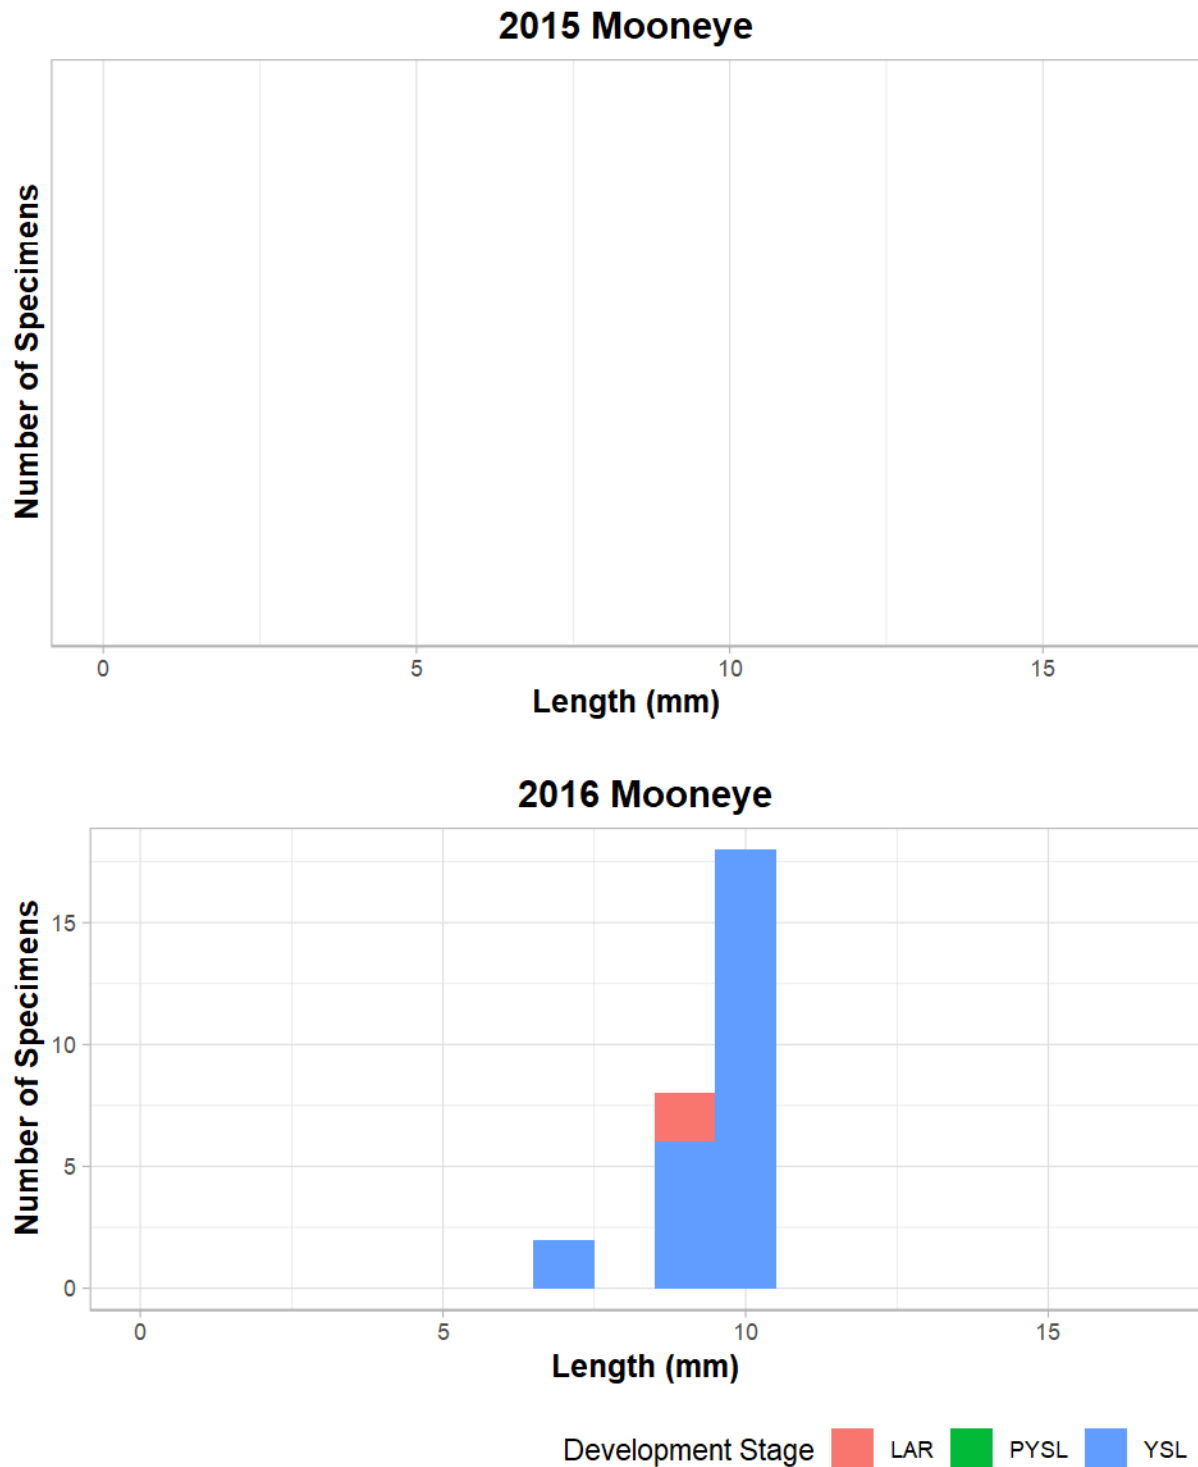

Figure 9 D-24 Length Histogram of Entrained Mooneye by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

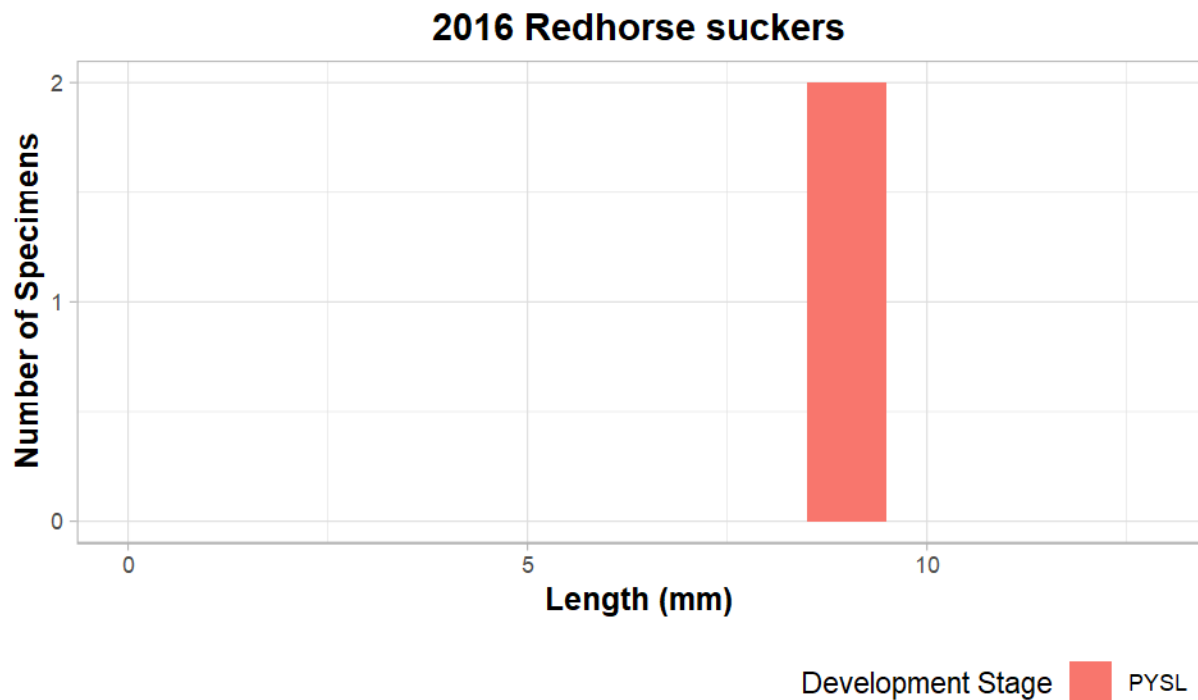

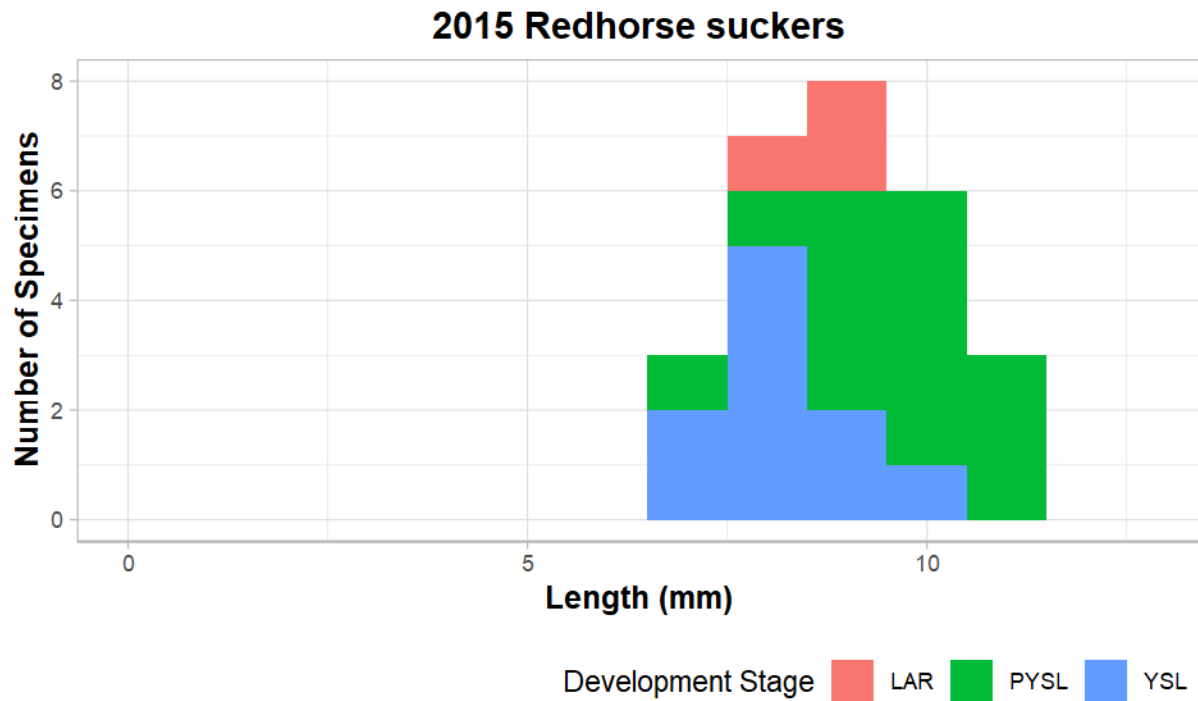

Figure 9 D-25 Length Histogram of Entrained Redhorses (*Moxostoma* sp.) by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

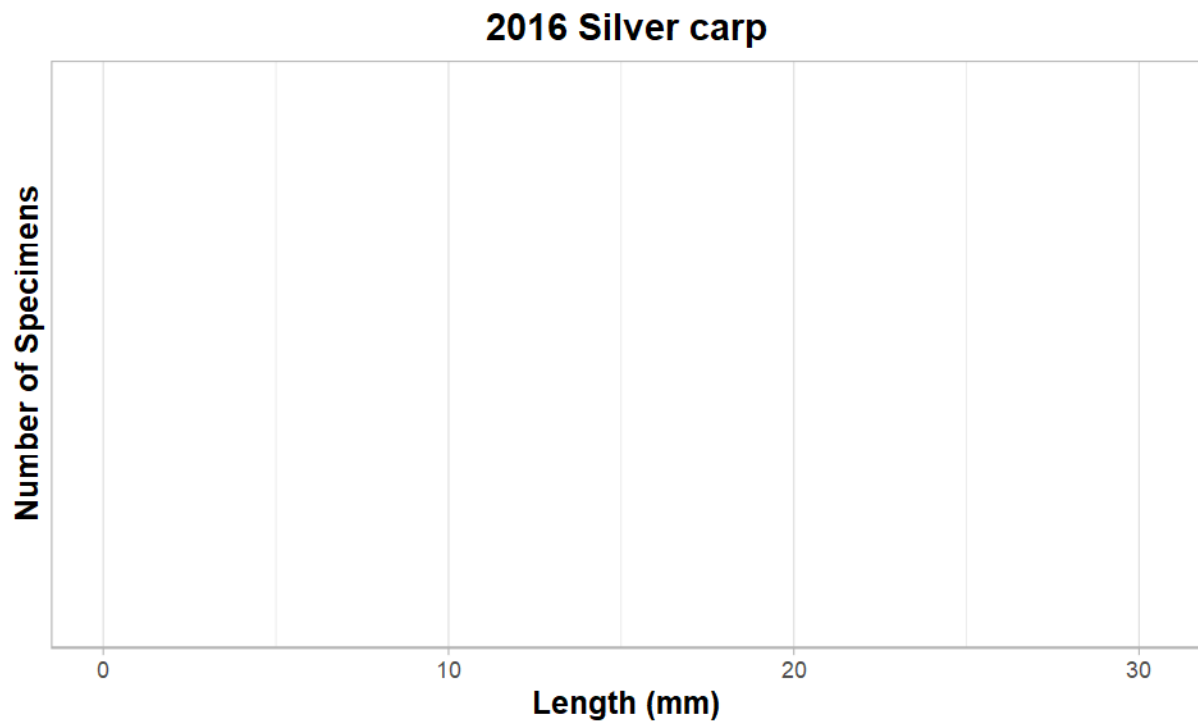

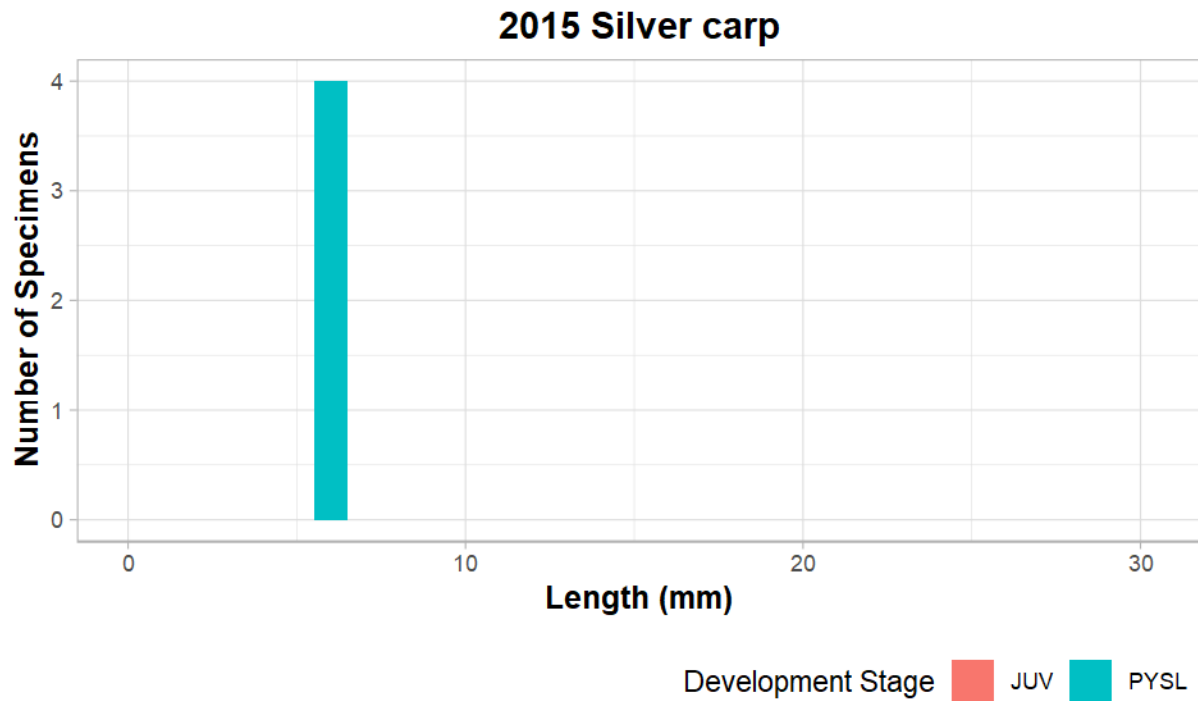

Figure 9 D-26 Length Histogram of Entrained Silver Carp by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

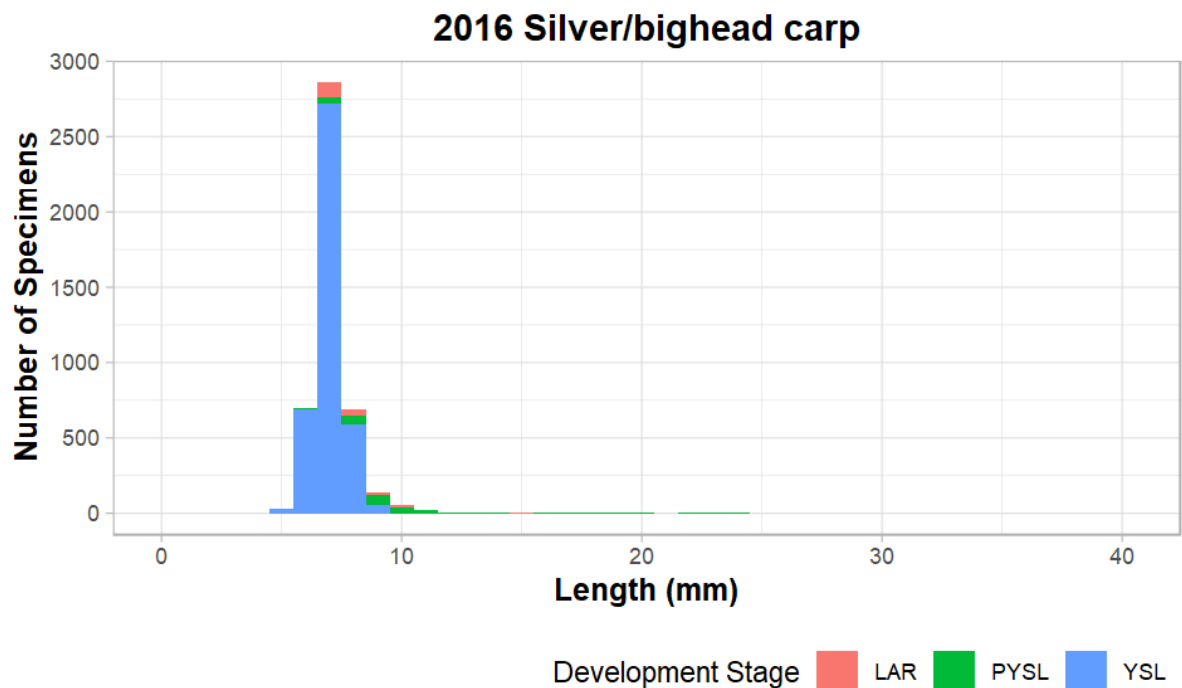

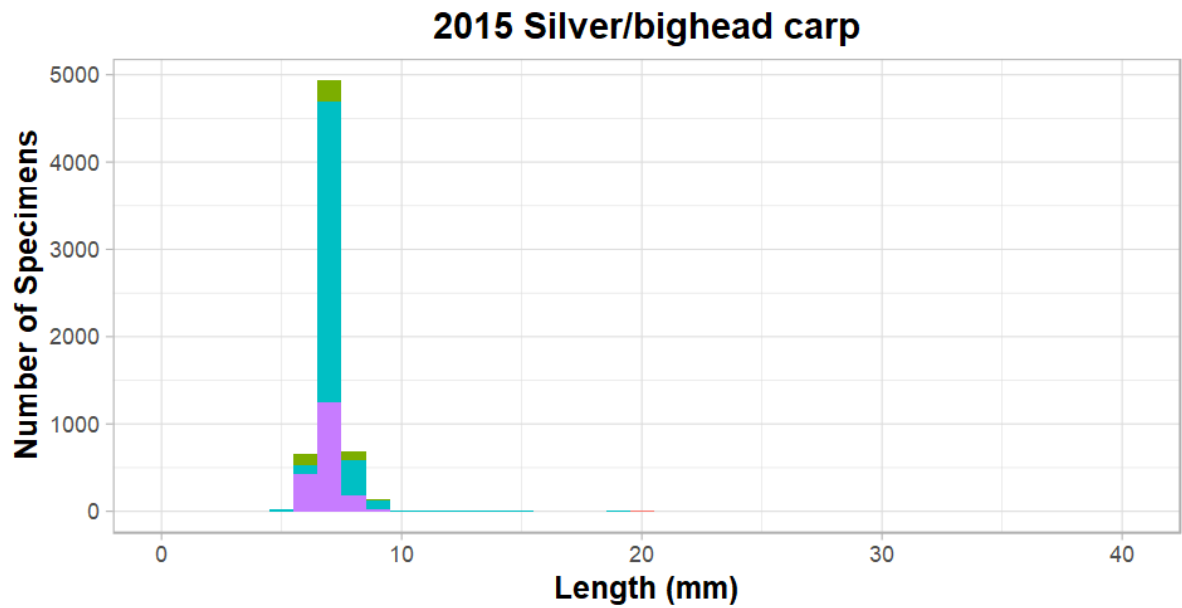

Figure 9 D-27 Length Histogram of Entrained Silver Carp and Bighead Carp (*Hypophthalmichthys* sp.) by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

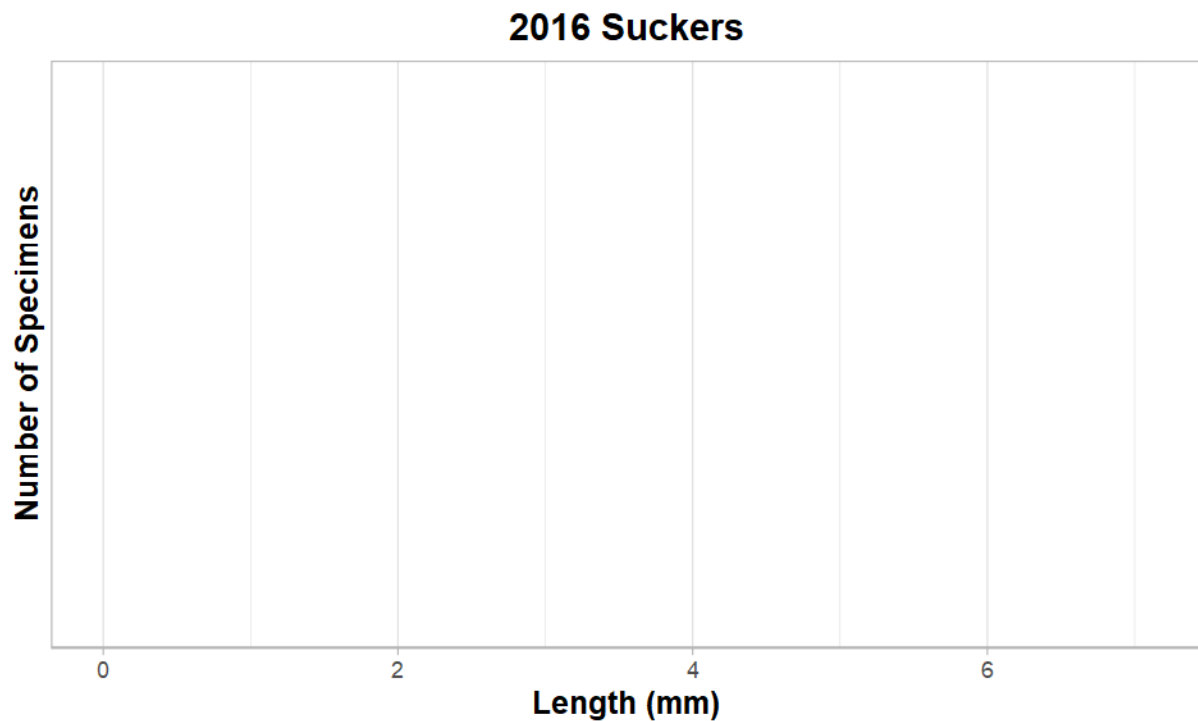

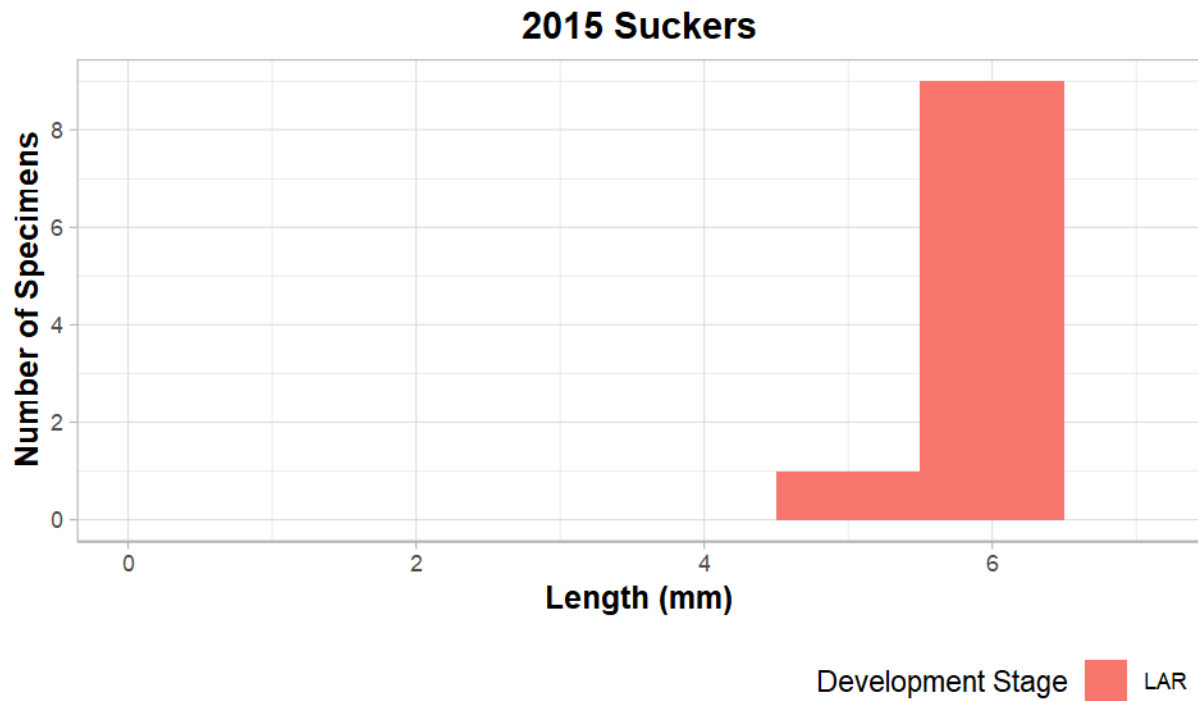

Figure 9 D-28 Length Histogram of Entrained Sucker Family (Catostomidae) Fishes by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

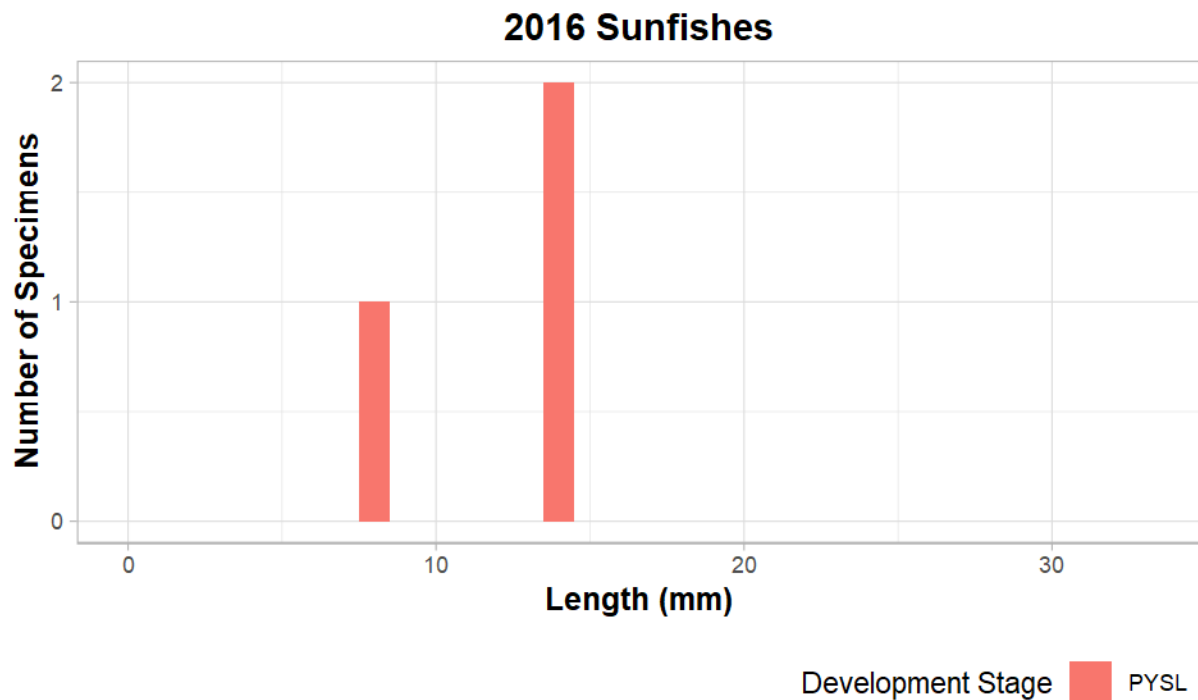

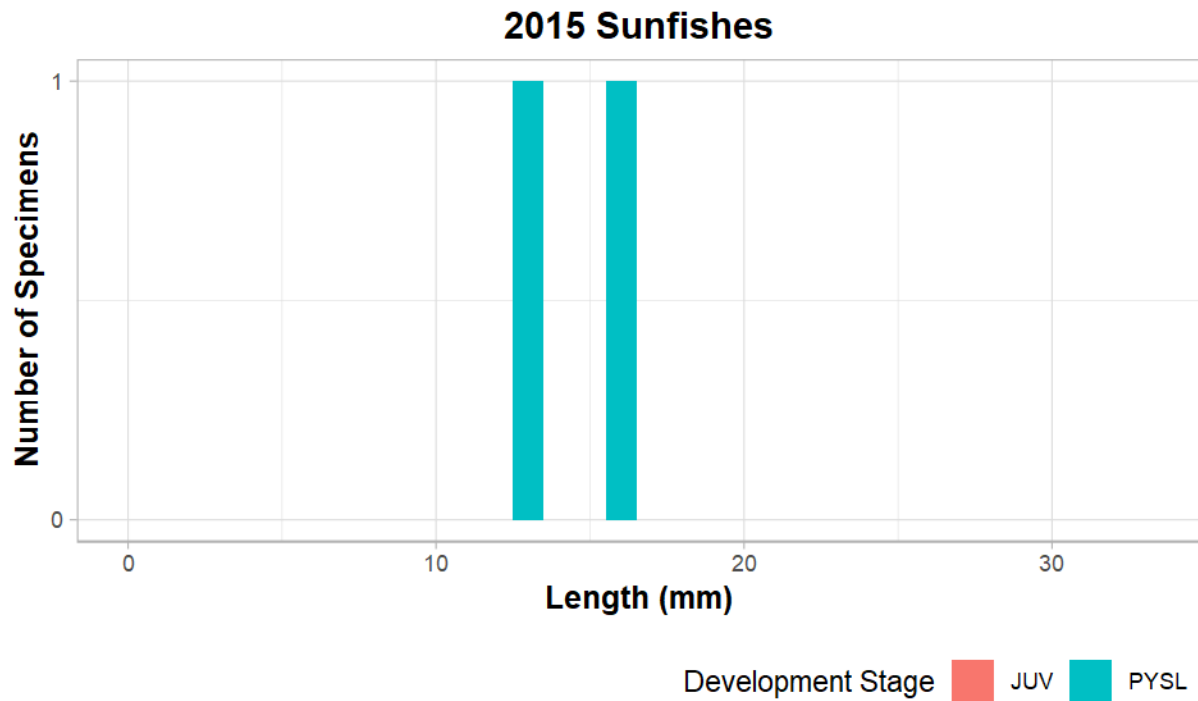

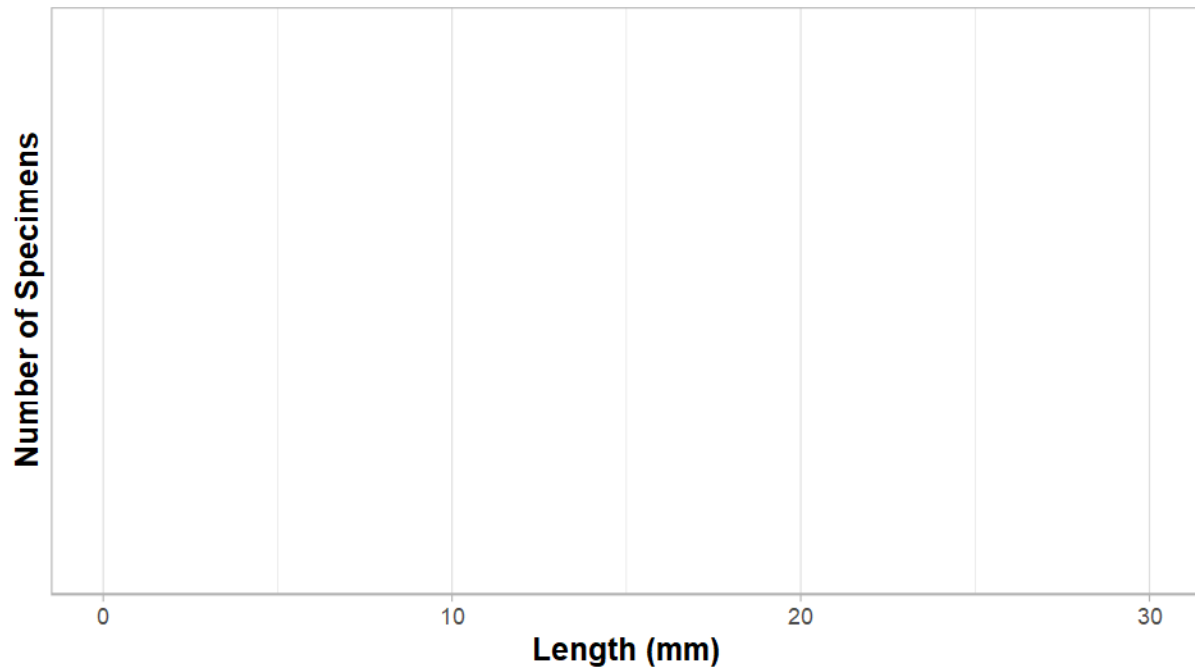

Figure 9 D-29 Length Histogram of Entrained Sunfish Family (Centrarchidae) Fishes by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

2015 Sunfishes (Lepomis)

2016 Sunfishes (Lepomis)

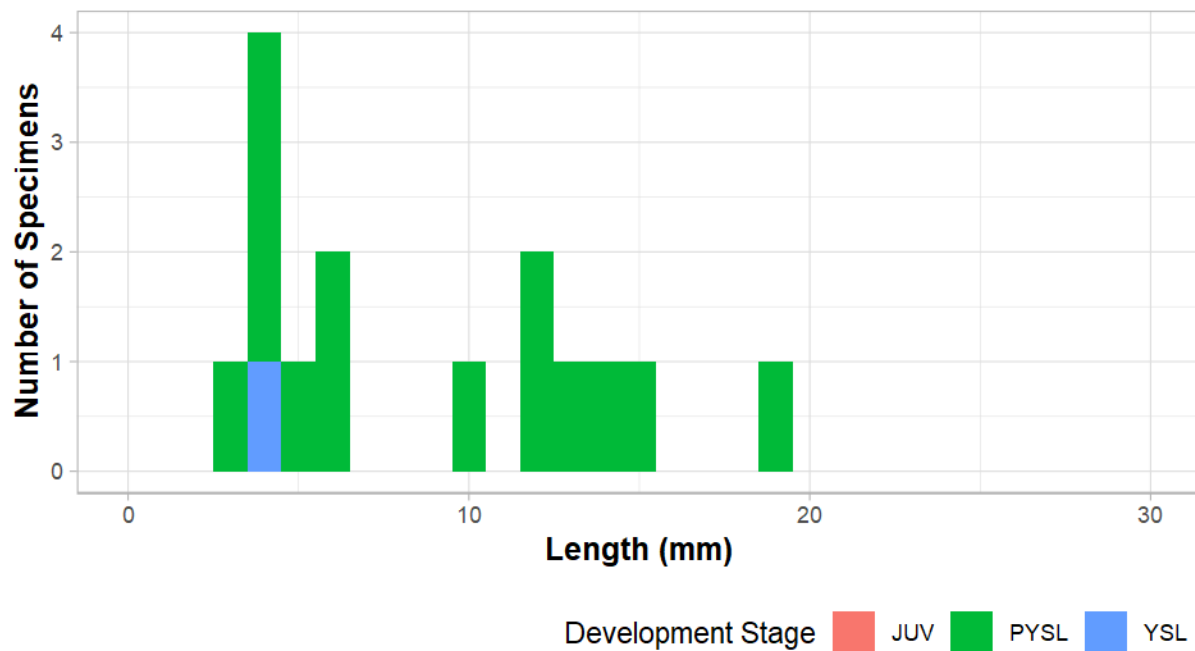

Figure 9 D-30 Length Histogram of Entrained Sunfishes (*Lepomis* sp.) by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

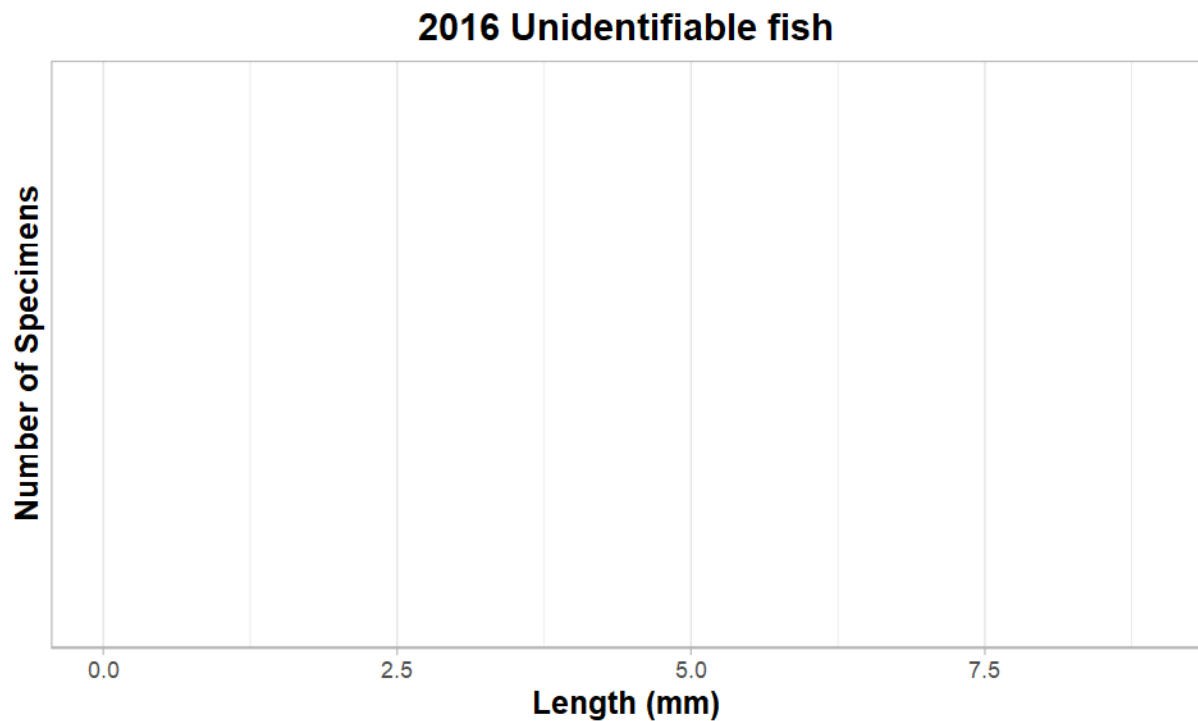

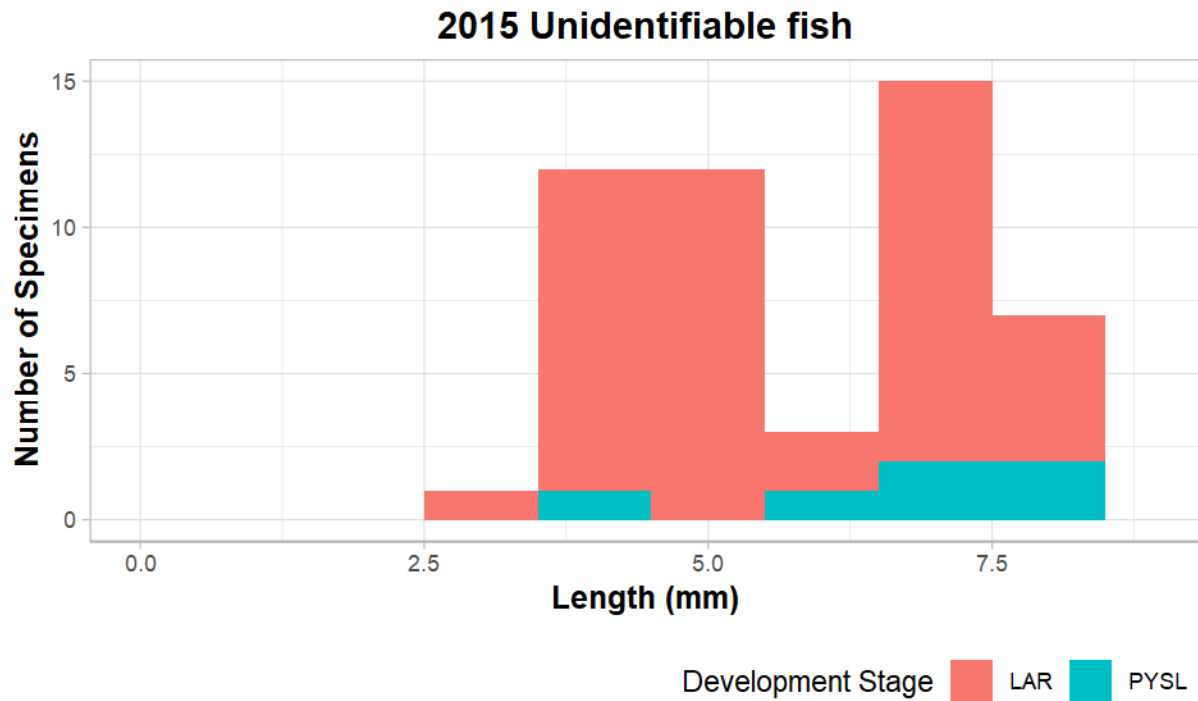

Figure 9 D-31 Length Histogram of Entrained Unidentifiable Fishes by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

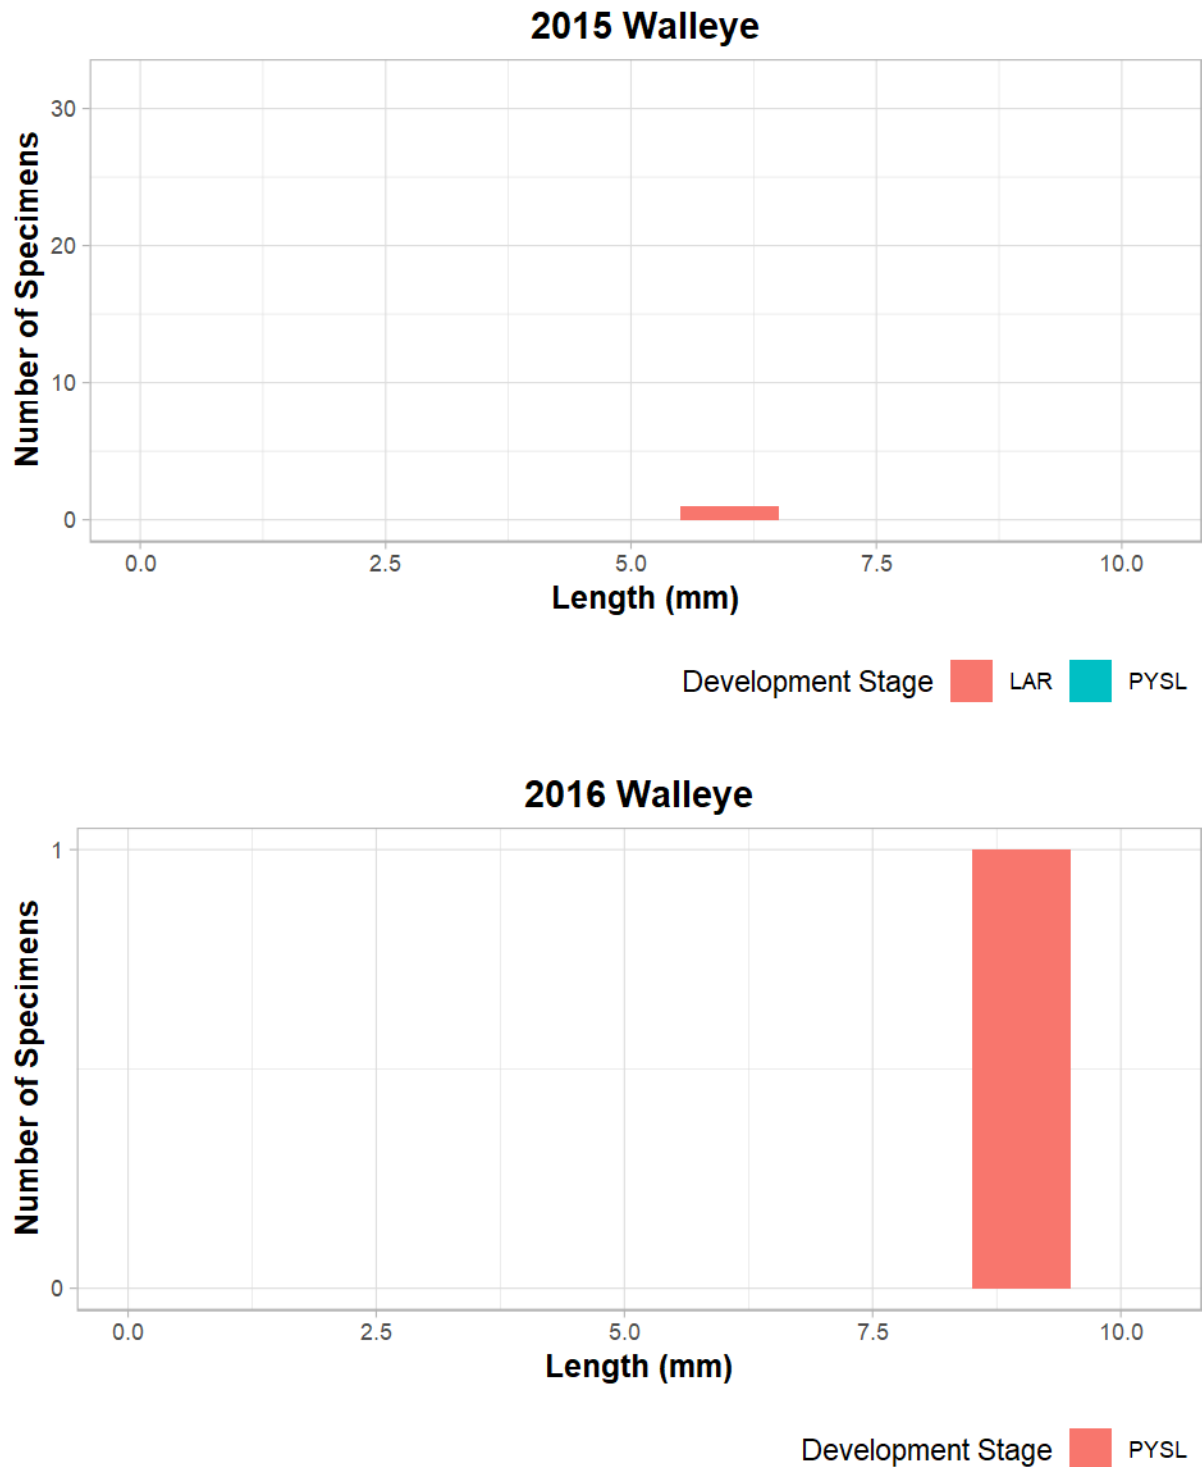

Figure 9 D-32 Length Histogram of Entrained Walleye by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

Figure 9 D-33 Length Histogram of Entrained Walleye and Sauger (*Sander* sp.) by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

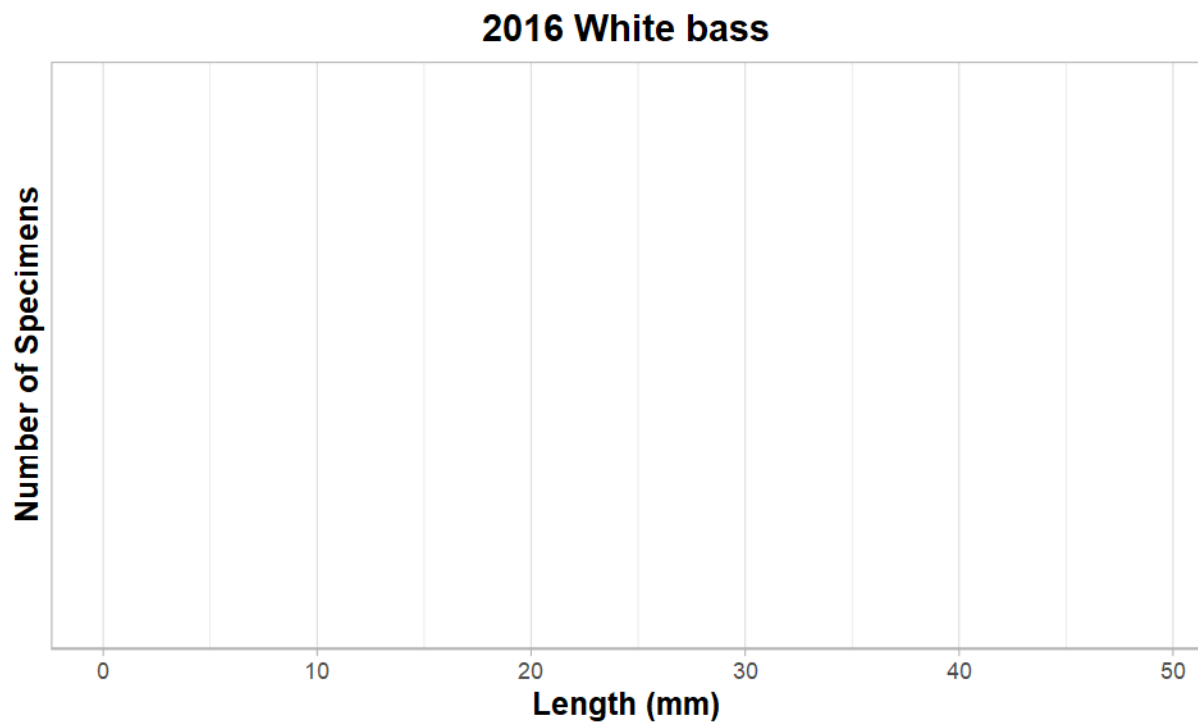

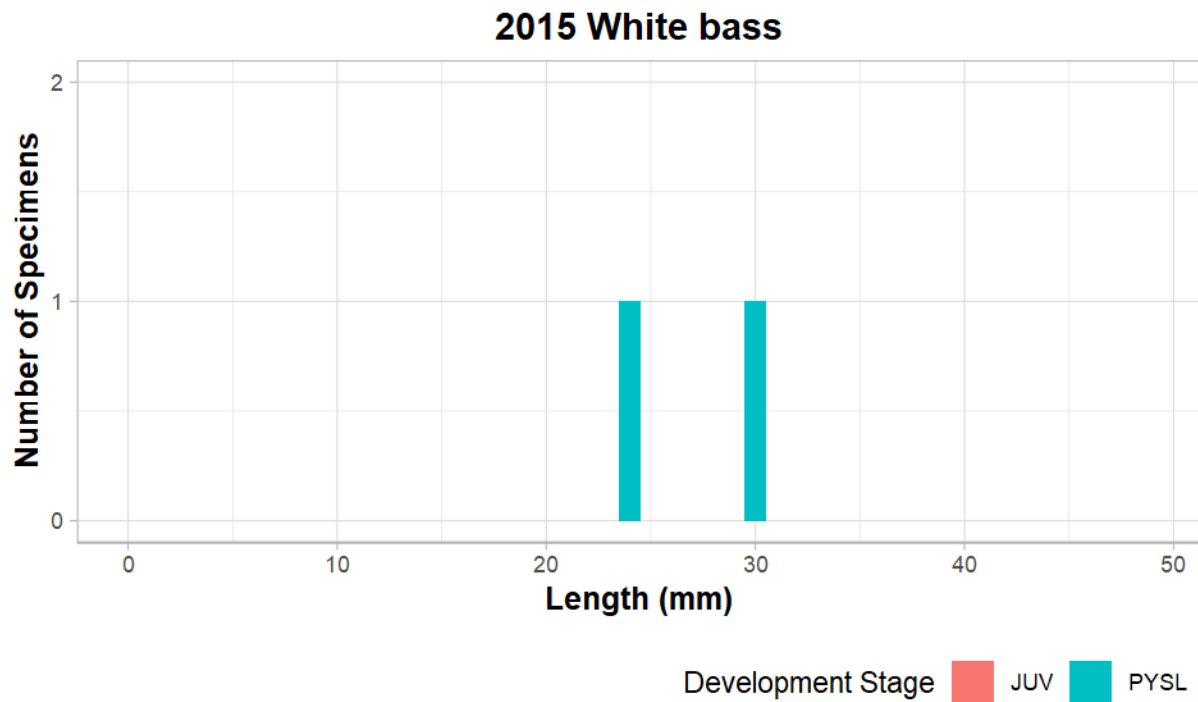

Figure 9 D-34 Length Histogram of Entrained White Bass by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.

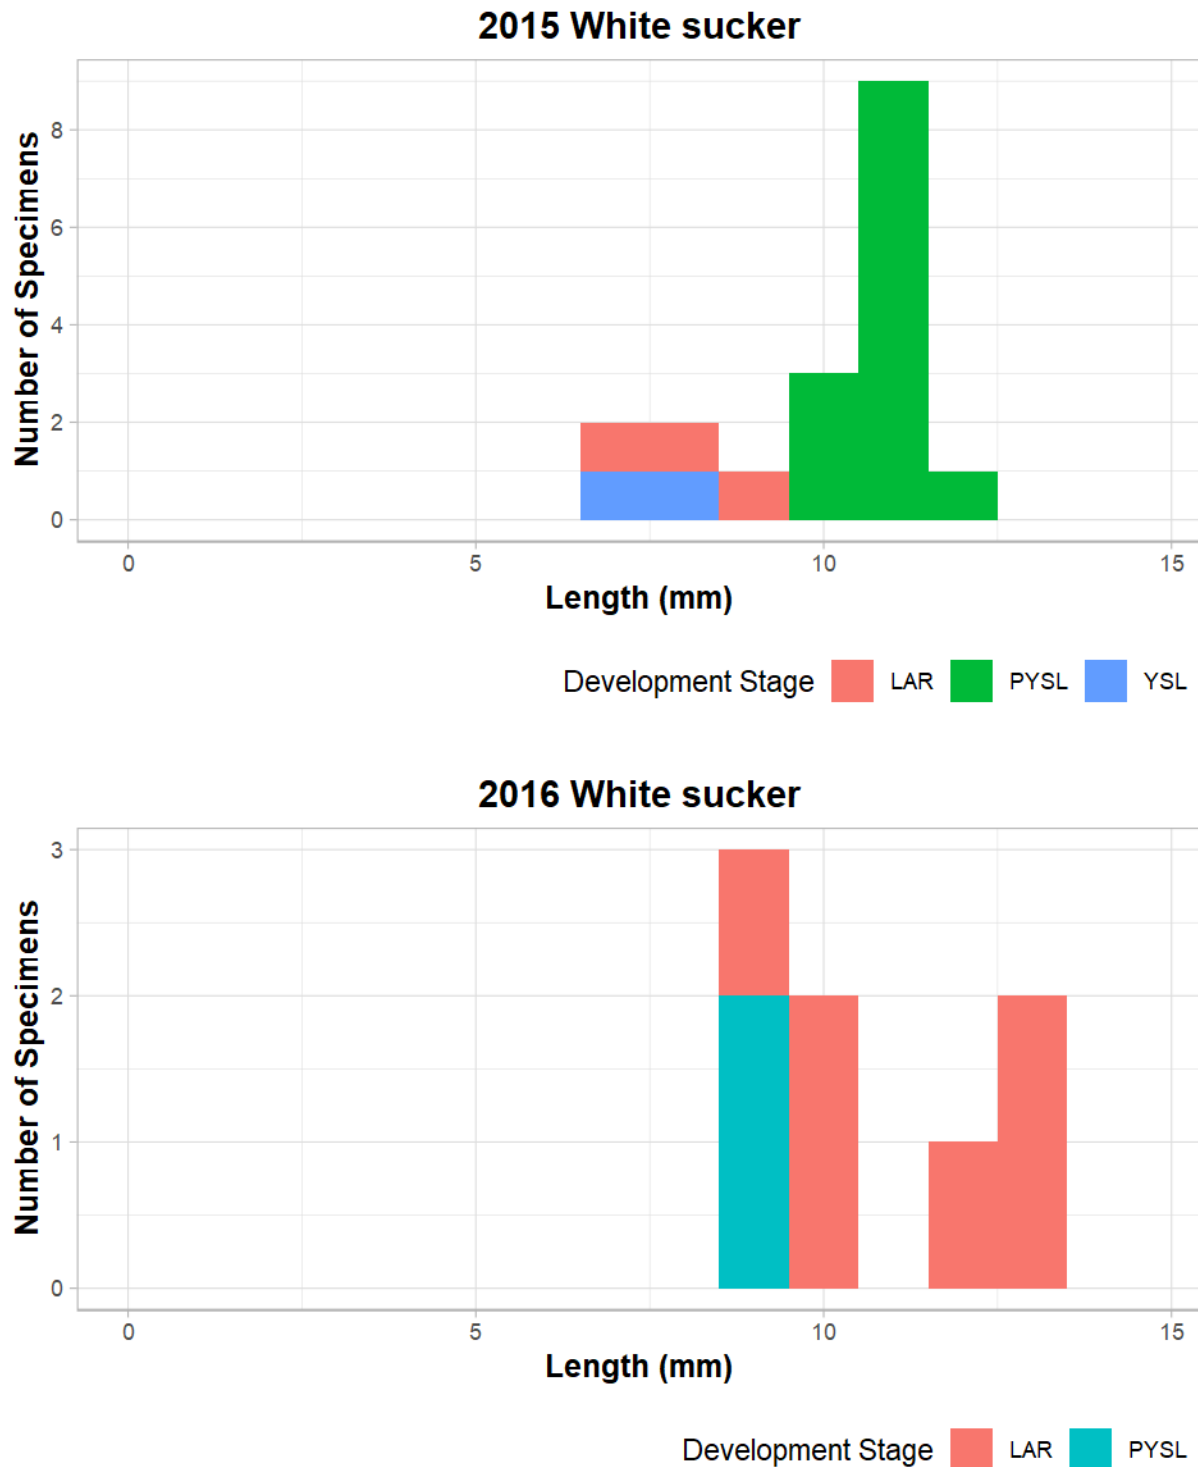

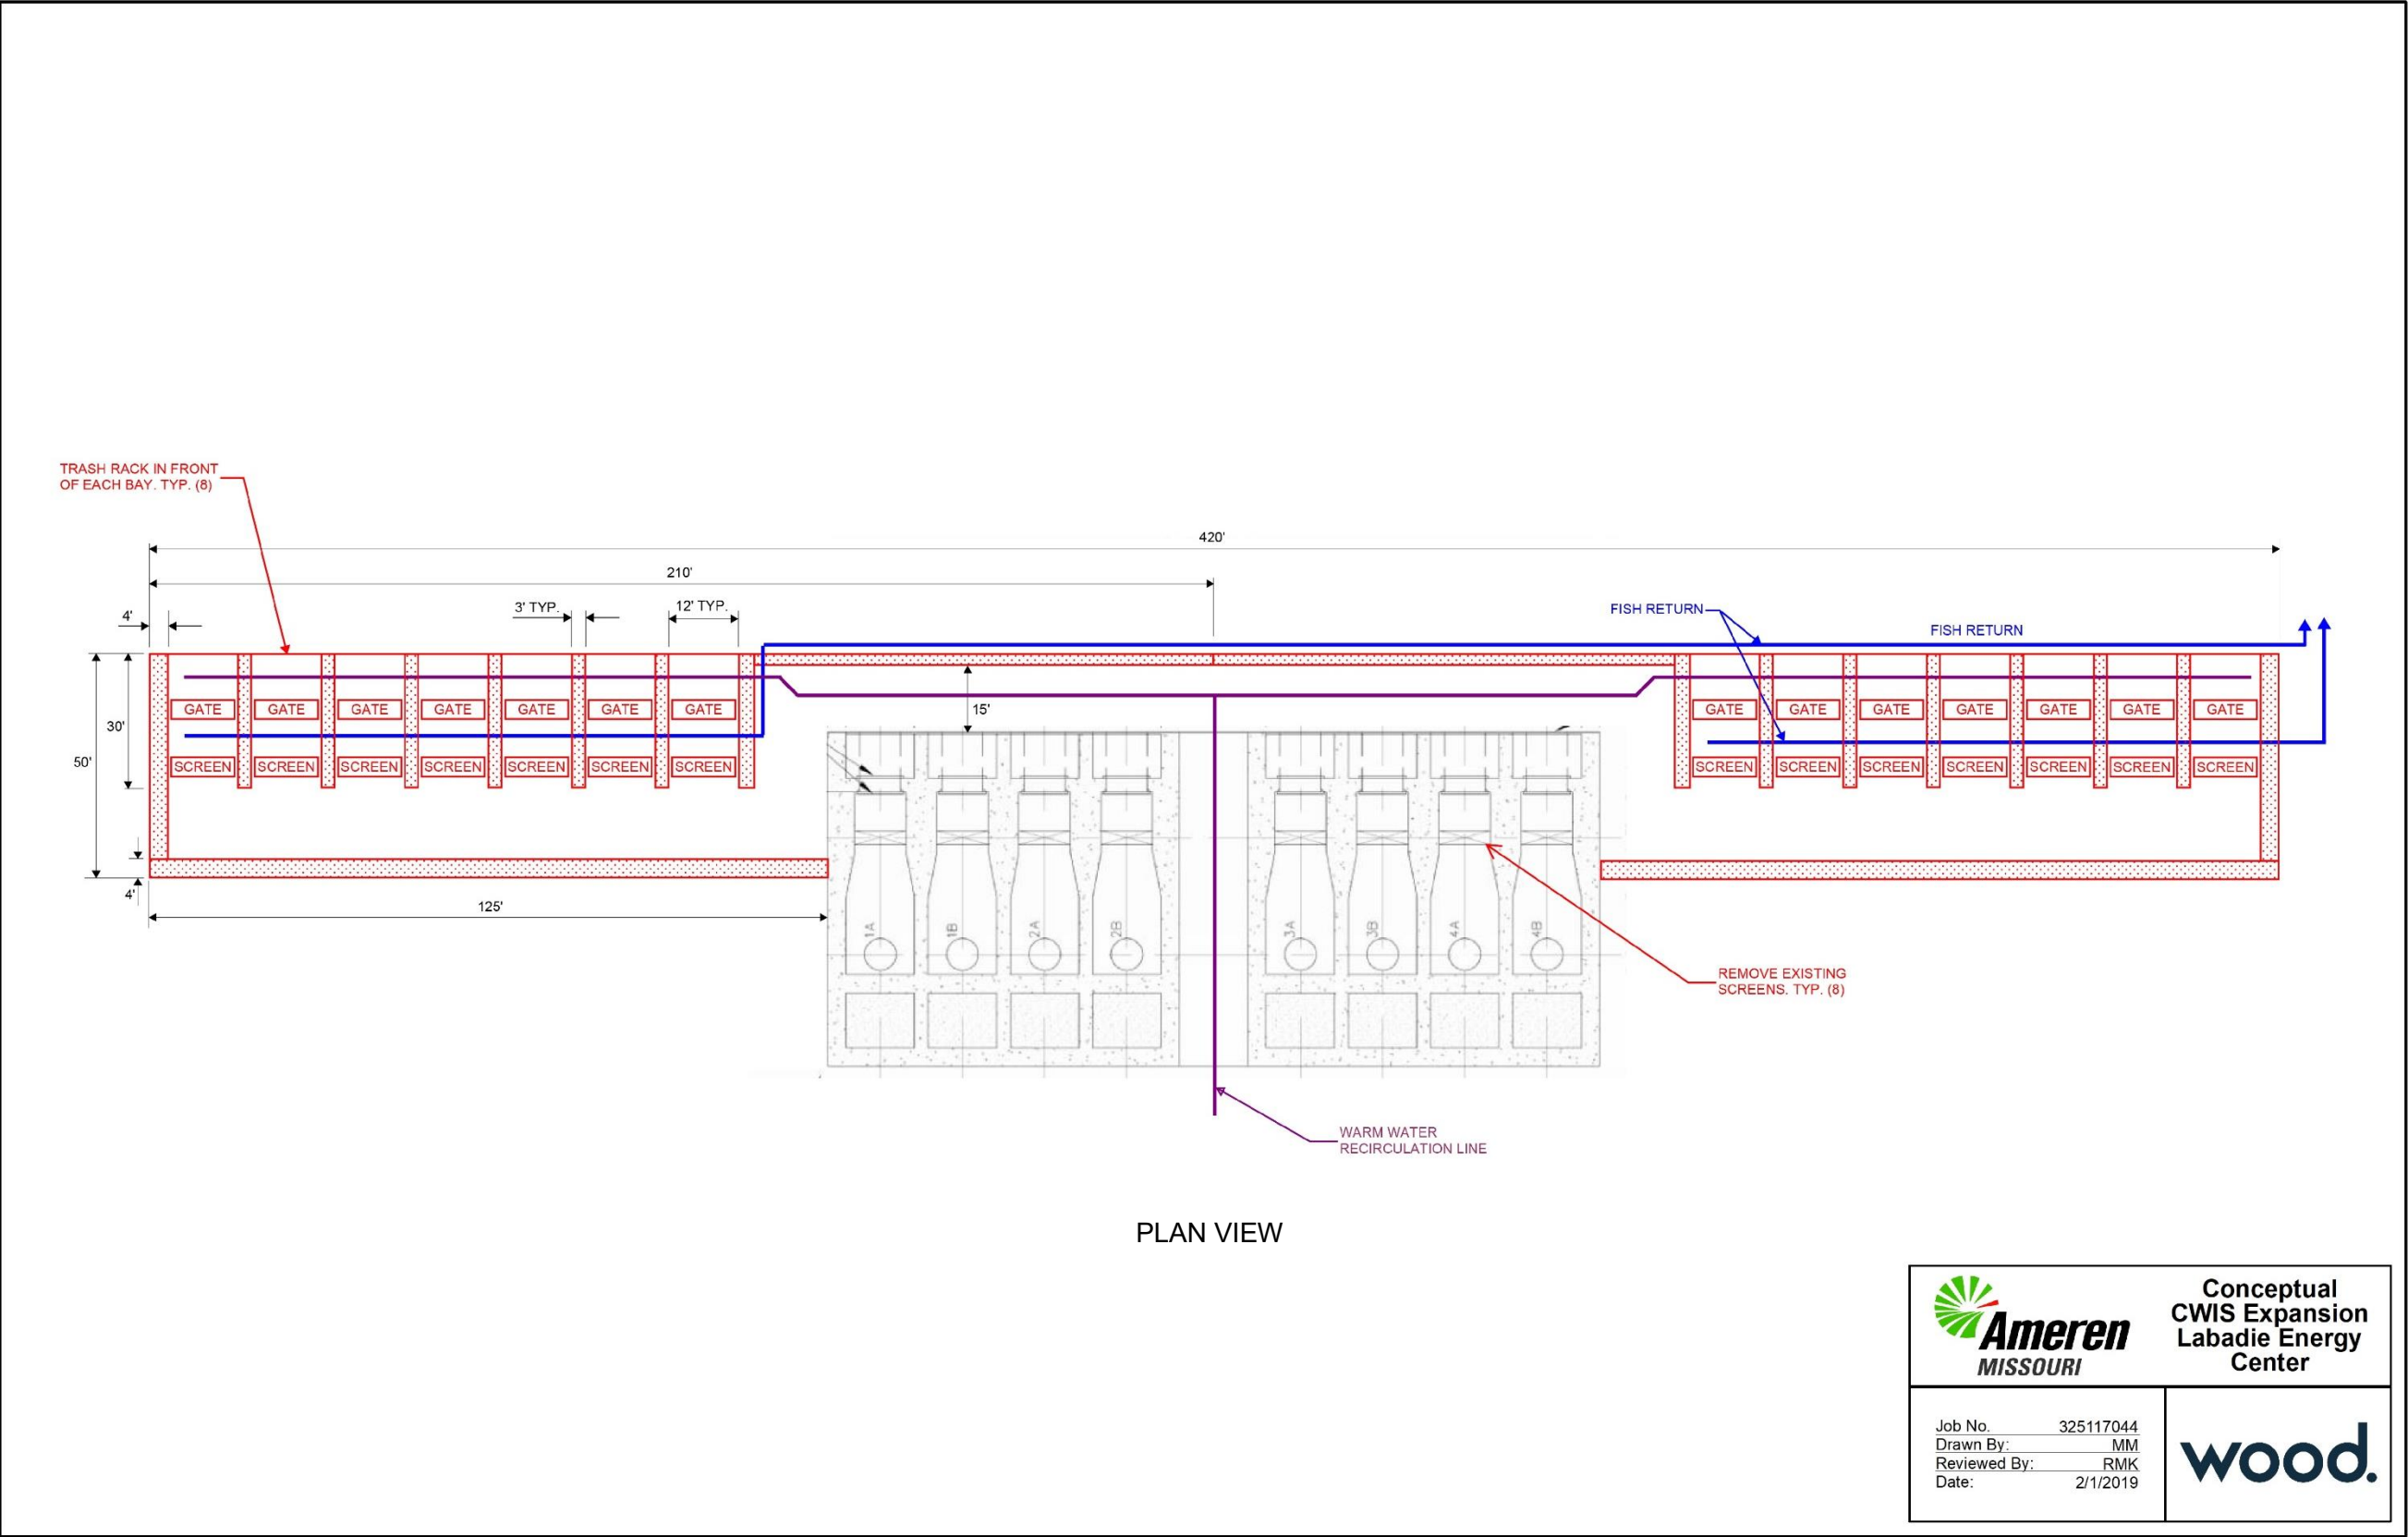

Figure 9 D-35 Length Histogram of Entrained White Sucker by Development Stages Collected During 2015 and 2016 Sampling Conducted at the LEC.
